PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

8142 PARATHYROID HORMONE AND GASTRIC MUCOSAL SURFACE ULTRASTRUCTURE. *(E.)* Frenning, B.; Johansson, H.; Ohrn, P. G. (Univ. Hosp., Uppsala, Sweden). *Upsala J. Med. Sci.* 79(2):90-93, 1974.

The gastric mucosal surface of rats given parathyroid hormone (40 USP U/100 g twice a day for 14 days, s.c.) was examined with a scanning electron microscope. Luminal surfaces of surface epithelial cells showed nonspecific damage consisting of mucus-covered microvilli and open crypts. Although the same changes were seen in some control specimens, the changes were more pronounced and the damaged cells more numerous in gastric mucosa from hormone-treated rats. The changes suggest that the decreased gastric secretion observed in rats after parathyroid hormone treatment is an effect of increased back-diffusion of hydrogen ions. The nonspecific damage may be related to the suggested ulcerogenic effect of the hormone.

8143 CHOLINESTERASE-RICH CELLS IN THE RAT FUNDIC MUCOSA. A LIGHT AND ELECTRON MICROSCOPICAL INVESTIGATION. *(E.)* Monga, G.; Bonfanti, S.; Bussolati, G. (Fac. Med. Surg., Univ. Turin, Italy). *Histochem. J.* 6(5):559-565, 1974.

Sections of rat fundic mucosa fixed in formaldehyde or glutaraldehyde-H_2C_2 and incubated in butylcholinesterase medium exhibited staining of numerous pyramidial or elongated epithelial cells in the lower 1/3 of the mucosa. The cells closely corresponded to the argyrophilic cells that stained with the Grimelius method. Electron microscopy showed that the cholinesterase-positive cells were localized in the perinuclear space, the Golgi saccules, throughout the cytoplasm, and occasionally at the plasma membrane of enterochromaffin-like cells. A-like endocrine cells were devoid of specific activity. If the argyrophilic reaction in endocrine cells is related to the presence of lipoproteins in cystoplasmic granules, the cholinesterase activity of enterochromaffin-like cells may be correlated with the argyrophilia of these cells. Cholinesterase activity at the plasma membrane level may relate to the mechanism of hormone release of the regulation of membrane permeability. It is also postulated that cholinesterase activity of enterochromaffin-like cells is correlated with the presence of a cholinergic mechanism of secretion.

8144 A SCANNING ELECTRON MICROSCOPIC STUDY OF NORMAL AND X-IRRADIATED GUINEA-PIG GASTRIC MUCOSA. *(E.)* Capoferro, R. (Rikshosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(6):533-538, 1974.

The scanning electron microscope was used to examine the ultrastructural surface aspects of the normal and of the irradiated gastric mucosa in the guinea pig. Four guinea pigs, weighing about 500 g, were subjected to irradiation of the stomach (dose 1540 R at skin, field size 4.5 X 5.5 cm at skin). Three and 5 weeks later, the animals were fasted for 16-24 hr, and a gastric lavage with isotonic saline was performed. They were then sacrificed and the stomach removed, and samples from different parts of the stomach examined by electron microscopy. The gastric mucosa of 2 non-irradiated control guinea pigs had an ultrastructural topography similar to that reported in other laboratory animals and man, without, however, the typical cobblestone appearance and with less pronounced superficial cell outlines. The mucosal surface of the stomach in the irradiated guinea pigs, however, was markedly irregular with the formation of small sessile polyps, and increased renewal and desquamation of mucus cells. The anomalous patterns of the surface structure may be correlated with similar conditions in human chronic atrophic gastritis.

8145 ULTRASTRUCTURAL CHANGES IN THE SMALL INTESTINES OF RATS WITH SELF-FILLING BLIND LOOPS. *(E.)* Gracey, M.; Papadimitriou, J.; Bower, G. (Princess Margaret Children's Med. Res. Fdn., Perth, Australia). *Gastroenterology* 67(4):646-651, 1974.

Transmission electron microscopy showed extensive damage to microvillous and cytoplasmic portions of enterocytes in specimens of jejunum from Wistar rats with a self-filling blind jejunal loop. The light and scanning electron microscopic appearance of these cells was essentially normal. The ultrastructural changes included variable degrees of distortion and denudation of microvilli, swelling and vesiculation of mitochondria, accumulation of lipid droplets in the apical portions of enterocytes, and distortion of Golgi material. The changes were patchy but occurred in 10-35% of enterocytes examined from the midvillus region of these animals. The results confirm that ultrastructural abnormalities occur in the small intestinal epithelium as a consequence of bacterial contamination of the upper gut. The abnormalities may contribute to intestinal malabsorption in patients with bacterial overgrowth in the upper gut.

8146 MORPHOLOGY AND CELL PROLIFERATION OF SUBEPITHELIAL FIBROBLASTS IN ADULT MOUSE JEJUNUM. I. STRUCTURAL FEATURES. *(E.)* Marsh, M. N.; Trier, J. S. (Harvard Med. Sch., Boston, Mass.). *Gastroenterology* 67(4):622-635, 1974.

The organization and morphology of subepithelial fibroblasts were investigated in adult Charles River mouse jejunum. Toluidine blue-stained 1μ Epon sections of osmium-fixed tissue were compared with electron micrographs of adjacent thin sections permitting precise identification of mesenchymal cells adjacent to crypt and villose epithelium. A continuous subepithelial fibroblast sheath (1-3 cells thick) was observed in the crypts and along the base of some villi. This sheath consisted of fibroblasts which appeared spindle-shaped when sectioned due to thin sheath-like processes which extended toward the periphery from the center of the cells. These cells were closely applied to the epithelial basal lamina and were surrounded by collagen. In contrast, no well-developed sheath was present along the middle and distal portions of the villi. Rather, various mesenchymal cell types (capillary endothelial cells, macrophages, and leukocytes), as well as fibroblasts, were located adjacent to the epithelial lamina. Furthermore, in contrast to the crypt region, collagen was sparse in the lamina of the villi. Thus, an organized subepithelial fibroblast sheath is seen only in the crypt region of mouse jejunum. It is not found throughout the mucosa as in the rabbit and human colon.

8147 STRUCTURE OF RAT LIVER SINUSOIDS AND ASSOCIATED TISSUE SPACES AS REVEALED BY SCANNING ELECTRON MICROSCOPY. *(E.)* Motta, P.; Porter, K. R. (Dept. Anat., Univ. Rome, Italy). *Cell Tissue Res.* 148(1):111-125, 1974.

The inner surface of sinusoids and adjacent hepatocytes from healthy adult albino rats were examined by scanning electron microscopy. The endothelial cells lining the sinusoids showed large numbers of fenestrations that varied greatly in size and arrangement. Some were very small (0.1 μM) and arranged in clusters; other, much larger fenestrae (1.0 μM) were divided by slender strands of cytoplasm. At sites where the large fenestrae were present a double endothelial lining was evident, suggesting a structural assurance against complete breakdown of the thin and fragile endothelial wall. Junctions between adjacent endothelial cells were not found in the preparations. The open continuity of the sinusoid was occasionally interrupted by slender extensions of cells morphologically distinct from the thin fenestrated endothelial cells. These had a characteristically textured surface and were thought to be stellate Kupffer cells. The scanning electron microscope images showed that the subendothelial spaces of Disse are larger than is evident from transmission micrographs. The space, limited on 1 side by hepatocytes with numerous microvilli and on the other by endothelial cells, appears to be only part of an extensive labyrinth of intercellular channels. These connect the more discrete spaces of Disse and extend into the narrow spaces between the hepatocytes. The total effect of this system is to expose the greater part of the liver cell surface to the blood filtrate. Microvilli populate the hepatocyte surfaces except for narrow margins which border the bile canaliculi. Whether their presence coincides with adsorbing surfaces and their absence with secreting surfaces remains to be determined.

8148 ELECTRON MICROSCOPY OF THROMBOCYTES IN THE ORTHOTOPIC PORCINE LIVER HOMOGRAFT DURING THE LATE REJECTION (PHAGOCYTOSIS OF THROMBOCYTES BY KUPFFER CELLS). *(E.)* Cossel, L. (Inst. Pathol, Karl Marx Univ., Leipzig, Germany). *Virchows Arch.* [*Pathol. Anat.*] 304(3):265-273, 1974.

Orthotopic porcine liver homograft was examined by electron microscopy 138 days after transplanation. Thrombocytes were found in sinusoids and at focal interruptions of the endothelial sinusoid lining or at the sinusoid wall, often in the vicinity of normally present endothelial pores. Basement-like structures were visible in the sinusoid wall near the thrombocytes and in the space of Disse between the endothelial lining and the hepatocytes. Apparently unaltered thrombocytes were also observed within Kupffer cells. Although there was an optically empty space between the thrombocyte cell membrane and the surrounding membrane of the Kupffer cell, both membranes were in close contact and appeared to be fused. The phagocytosis of the thrombocytes may represent an increased reaction of the transplant (Kupffer Cells) against host cells (thrombocytes) circulating in the blood. Increased phagocytosis of thrombocytes by Kupffer cells of the transplanted liver might adversely affect the thrombocytopoiesis of the host organism. This would entail blood clotting disturbances and thus impair the long-term prognosis.

8149 ULTRASTRUCTURAL STUDY OF HEPATIC MITOCHONDRIAL ABNORMALITY IN SWINE TREATED WITH CLOFIBRATE. *(E.)* Lee, K. J.; Kim, D. N.; Lee, K. T. (Albany Med. Coll., N.Y.). *Exp. Mol. Pathol.* 20(3): 387-396, 1974.

Hepatic ultrastructural changes associated with the hypocholesterolemic effects of clofibrate were investigated in swine fed a mild atherogenic diet containing 2.4 g cholesterol/day. After 25 days on the diet, serum cholesterol levels rose significantly in all 7 animals and were not lowered by administration of 0.5 g/day clofibrate for 10 days. In contrast, 2 g/day clofibrate for 35 days significantly reduced the mean serum cholesterol level from 308 mg/deciliter to 123 mg/deciliter. Characteristic ultrastructural changes were observed in 17% of hepatocellular mitochondria after 6 weeks of clofibrate treatment. The most frequent mitochondrial alteration was the presence of discrete bundles of tubular or spiral structures which appeared at random in orientation. The number of hepatocellular microbodies increased moderately in clofibrate-treated swine but no structural changes were noted. In some hepatic cells smooth endoplasmic reticulum appeared hyperplastic and rough endoplasmic recticulum slightly dilated.

8150 LIGHT AND ELECTRON MICROSCOPIC STUDIES ON THE DEVELOPMENT OF PERIPORTAL BILE DUCTS OF THE HUMAN EMBRYO. *(E.)* Enzan, H.; Ohkita, T.; Fujita, H.; Iijima, S. (Res. Inst. Nucl. Med. Biol., Hiroshima Univ., Japan). *Acta Pathol. Jap.* 24(4): 427-447, 1974.

To clarify the development of the periportal bile duct in the human embryo, liver tissue from a 13-week-old embryo was examined by light and electron microscopy. A plate-like arrangement of single layered biliary epithelial cells was seen on the surface of periportal liver parenchyma. The space between the plate and adjacent hepatoblasts was small (1-2 μ in diameter). At other periportal sites large biliary spaces (lumens 7-10 μ in diameter) were lined with numerous biliary epithelial cells and a few hepatoblasts. The biliary epithelial cell in these spaces was cuboidal or columnar with a slight apical narrowing at the luminal surface. No intermediate cells between biliary epithelial cells and hepatoblasts were detected in the small or large biliary spaces. The primary bile duct was directly connected with some of the large biliary spaces, and in these areas mitotic figures of the biliary epithelial cells were occasionally found. New bile ducts ran almost parallel to the surface of the liver parenchyma and sometimes contacted the surface of the hepatoblast. It is concluded that the periportal bile duct is formed by the proliferation of the biliary epithelial cells surrounding the biliary space.

8151 THE ANATOMY AND INNERVATION OF THE SPHINCTER OF ODDI IN THE DOG AND CAT. *(E.)* Kyosola, K.; Rechardt, L. (Dept. Anat., Univ. Helsinki, Finland). *Am. J. Anat.* 140(4):497-522, 1974.

The fine three-dimensional structural arrangement of the intrinsic cholinergic innervation system of the sphincter of Oddi was studied in 25 adult cats and 5 adult dogs by microdissection and histological staining techniques and by demonstrating nonspecific cholinesterases in serial sections. The most important morphological features with respect to function were the tapering of the terminal ductus choledochus into a nozzle, the existence of concentric retrograde saccules around the ampulla and intramural part of the bile duct, and the complex construction of the sphincters. This structural arrangement permits an active suction-pressure pumping for evacuation of bile and pancreatic juice and is at the same time effective in preventing regurgitation of the duodenal fluid. If the orificium of the ampulla is obstructed, this structural arrangement probably facilitates regurgitation, especially into the pancreatic duct. The intrinsic cholinergic nervous apparatus of the choledocho-duodenal junction was extremely rich in acetylcholinesterase-positive nerve cells, especially in comparison with the muscular layer of the gut wall, probably indicating the complex motor (and possibly associated sensory) functions of the sphincters in contrast to only slow gross contractions of the gut. The finely graded complex interactions of the various muscle components of the choledocho-duodenal junctions of the dog and cat appeared to be regulated by connecting and integrating neural elements between individual smooth muscle units.

ABSORPTION–EXCRETION–TRANSPORT

8166 STUDIES ON THE ATPase ENZYME SYSTEM IN HUMAN INTESTINAL EPITHELIAL CELLS. *(E.)* Mooney, P.; McCarthy, C. F. (Reg. Hosp., Galway, Ireland). *Clin. Chim. Acta* 56(1):37-47, 1974.

Human intestinal epithelial cells were fractionated to yield a soluble and particulate cell fraction, and a brush border fraction. (Na$^+$-K$^+$)-stimulated, ouabain sensitive ATPase was located in the brush border and soluble cell fractions. Mg^{2+}-ATPase occurred throughout the epithelial cell. This enzyme was inhibited by Ca^{2+} in the brush border fraction but was activated by Ca^{2+} and Mg^{2+} in the particulate cell fraction. The (Na$^+$-K$^+$)-ATPase systems were separated and partially purified using Sephadex G-100. The brush border and soluble enzymes have different molecular weights, different K_m values for ATP, and different pH optima. The brush border enzyme is more stable to temperature and to aging, whereas the soluble ATPase, naturally unstable, can be stabilized by the addition of sucrose. These differences indicate that the human intestinal epithelial cells contain 2 distinct types of (Na$^+$-K$^+$)-ATPase. It is suggested that soluble (Na$^+$-K$^+$)-ATPase may function as a mobile carrier in the transport of sugar into the mucosal wall.

8167 THE RESPONSE OF THE SMALL INTESTINE TO VITAMIN D. CORRELATION BETWEEN CALCIUM-BINDING-PROTEIN PRODUCTION AND INCREASED CALCIUM ABSORPTION. *(E.)* Emtage, J. S.; Lawson, D. E. M.; Kodicek, E. (Dunn Nutr. Lab., Cambridge, England). *Biochem. J.* 144(2):339-346, 1974.

Intestinal supernatants from chicks given vitamin D (5 µg intracardially) were examined with a radioimmunological technique capable of estimating calcium-binding-protein concentrations as low as 1 µg/g wet weight. Calcium-binding-protein was not detectable at 8 hr but was present after 12 hr at a concentration of 8.6 µg/g wet weight; in agreement with this an increase in calcium absorption due to vitamin D was detected at 12 hr but not at 8 hr. Synthesis of calcium-binding-protein was also monitored directly by incubating intestinal polyribosomes from vitamin D-treated chicks with ^{125}I-anti-(calcium-binding-protein) and then separating the polyribosomes on sucrose gradients. Calcium-binding-protein was detected on the polyribosomes, as nascent polypeptide chains, as early as 8 hr after vitamin D administration. Further, the binding reaction indicated a near linear increase in the calcium-binding-protein synthesizing capacity over a 16-hr period. From the amount of calcium-binding-protein present 12 and 24 hr after vitamin D administration, production of calcium-binding-protein mRNA was calculated at approximately 1 M/min/intestinal cell. The high correlation between initiation of calcium-binding-protein synthesis and stimulation of calcium absorption by vitamin D emphasizes the importance of calcium-binding-protein in calcium transport.

8168 INFLUENCE OF SODIUM AND PARATHYROID HORMONE ON CALCIUM RELEASE FROM INTESTINAL MUCOSAL CELLS. *(E.)* Birge, S. J.; Switzer, S. C.; Leonard, D. R. (Jewish Hosp. St. Louis, Mo.). *J. Clin. Invest.* 54(3):702-709, 1974.

The influence of sodium and parathyroid hormone on the calcium transport process was investigated in duodenal mucosal epithelium of 3.5-week-old Wistar rats. The procedure permitted the direct measurement of both the rate of uptake and release of ^{45}Ca by mucosal cells. Incubations were carried out with intact intestinal segments, thus preserving the normal structural morphology and cell-to-cell interactions. In terminating the incubation for either uptake or release studies, the mucosal epithelial tissue was removed to the level of the crypt-villus junction and then was rapidly dispersed. The initial rate of uptake characterized a calcium pool with a half-time of saturation of less than 2 min. The entry of ^{45}Ca into this pool was inhibited by sodium cyanide and ethacrynic acid and was stimulated by the removal of chloride ion from the incubation. The initial rate of labeled calcium release was also inhibited by sodium cyanide and removal of sodium ions from the incubation. Parathyroid hormone administration enhanced the release of ^{45}Ca from cells prepared from parathyroidectomized animals. These findings suggest that calcium transport across the brush border and basal-lateral membranes are identifiable components of the kinetics of ^{45}Ca uptake and release from intestinal mucosal cells and that parathyroid hormone stimulates a sodium-dependent mechanism of calcium transport across the basal-lateral membranes.

8169 IDENTIFICATION OF AN INTESTINAL SODIUM AND CALCIUM-DEPENDENT PHOSPHATASE STIMULATED BY PARATHYROID HORMONE.

(E.) Birge, S. J.; Gilbert, H. R. (Jewish Hosp. St Louis, Mo.). *J. Clin. Invest.* 54(3):710-717, 1974.

Basal-lateral membranes were prepared from intestinal homogenates of 3.5-week-old Wistar rats (maintained on a calcium-deficient diet for 3 days and fasted overnight before sacrifice) to identify the enzyme which mediates the parathyroid hormone-sensitive active transport of calcium across the basal-lateral membrane of the intestinal epithelial cell. After parathyroidectomy, animals were given s.c. injections either of parathyroid extract (30 U) or 0.3 ml of 0.2% phenol and 1.6% glycerin in saline 4 hr before sacrifice to evaluate the influence of exogenous parathyroid hormone. An alkaline phosphatase was identified which utilized ATP as a substrate and was dependent on both sodium and calcium ions, with optimum enzyme activity at 200 mM and 0.04 mM, resp. The enzyme's activity decreased with advancing animal age and with removal of the parathyroid glands; this is consistent with a decreased rate of ^{45}Ca release from mucosal cells under the same experimental conditions. Calcium binding to basal-lateral membrane fragments was also sodium dependent and enhanced by the prior administration of parathyroid extract. The consistent correlation between the rate of calcium transport across the basal-lateral membrane of the mucosal cell and the activity of this sodium- and calcium-dependent phosphatase under a variety of experimental conditions suggest that this enzyme may mediate the parathyroid hormone-sensitive active transport of calcium across the intestine.

8170 LIPID ABSORPTION IN NEWBORN YOUNG OF GUINEA PIGS FED A PROTEIN-DEFICIENT DIET DURING GESTATION.

(E.) Zeman, F. J.; Widdowson, E. M. (Dunn Nutr. Lab., Cambridge, England). *Biol. Neonate* 24(5/6):344-353, 1974.

Absorption of ^{14}C-oleic acid (1 mM miscellar solution) and ^{14}C-triolein (60 mM emulsion) administered through duodenal cannula was measured in newborn young of guinea pigs which had been adequately nourished or deprived of protein in the last half of pregnancy. Protein-deficient animals showed significantly greater absorption, transfer, and total uptake of both lipids on the basis of amount/g intestinal tissue/min or amount/g body weight/min. In animals of the deficient group, villi of the jejunum were longer, narrower, and more numerous than in the controls, providing a morphological basis for some of the observed increase.

8171 FATTY ACID UPTAKE AND ESTERIFICATION BY PROXIMAL AND DISTAL INTESTINE IN BILE FISTULA RATS.

(E.) Brand, S. J.; Morgan, R. G. H. (Dept. Physiol., Univ. Western Australia, Nedlands). *Biochim. Biophys. Acta* 369(1):1-7, 1974.

The uptake and reesterification of ^{3}H-oleic acid (1 mM) was studied in intestinal sacs from the duodenojejunum and ileum of control Wistar rats and from rats provided with bile fistulas 48 hr previously. In addition, levels of 2 enzymes involved in the reesterification of absorbed fatty acid, acyl-coenzyme A (CoA):monoglyceride acyl transferase and acyl-CoA synthetase, were measured in proximal and distal intestine from control and bile-diverted animals. Ileal sacs from bile-diverted rats absorbed significantly more fatty acid than ileal sacs from controls (0.481 *versus* 0.382 µM/g weight tissue/15 min) and also reesterified significantly more fatty acid (0.149 *versus* 0.092 µM/g wet weight tissue/15 min). The increased ileal uptake was associated with an increase in the level of acyl-CoA synthetase and a decrease in the level of acyl-CoA:monoglyceride acyl transferase in the distal intestine of rats with bile fistulas compared with controls. These changes in ileal enzyme activity may result from changes in the composition of the lipid mixture absorbed by the distal ileum when bile is diverted. The increased enzyme activity may in turn promote uptake by increasing the rate of handling of absorbed lipid.

8172 A DISTINCT D-FRUCTOSE TRANSPORT SYSTEM IN ISOLATED BRUSH BORDER MEMBRANE.

(E.) Sigrist-Nelson, K.; Hopfer, U. (Biochem. Lab., Eidgenossische Tech. Coll., Zurich, Switzerland). *Biochim. Biophys. Acta* 367(2):247-254, 1974.

The transport of D-fructose was studied in isolated intestinal epithelial brush border membrane of Sprague-Dawley rats. The rate of D-fructose entry was slower than D-glucose but faster than L-glucose or D-mannitol. D-Fructose uptake, measured after 45-sec incubation, was linear up to and saturable above 200 mM, while D-mannitol uptake continued to be linear under identical incubation conditions. Uptake of labeled D-fructose was stimulated in D-fructose-preloaded membranes and unaffected in D-glucose-preloaded membranes. Conversely, D-glucose transport was enhanced in the D-glucose-preloaded membranes and unaltered in the D-fructose-preloaded membranes. D-Glucose uptake was stimulated approximately 3-fold by Na$^+$ and strongly inhibited by phlorizin, whereas neither Na$^+$ nor phlorizin influenced D-fructose uptake. None of the sugars tested (D-mannitol, D-glucose, D-galactose, D-fructose, L-sorbose, or D-tagatose) at 100:1 test inhibitor-to-substrate ratio decreased D-fructose transport. With the same membrane preparations, D-glucose transport was inhibited 75% by D-galactose. The results suggest the existence of a distinct D-fructose transport system, separate from that of D-glucose.

8173 THE ULTRASTRUCTURE AND PERMEABILITY FOR COLLOIDAL CARBON OF INTESTINAL SUBMUCOSAL ARTERIOLES IN RATS.

(E.) Thorball, N.; Olsen, F. (Anat. Dept. C, Univ. Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 82(5):627-636, 1974.

The fine structure and the permeability to colloidal carbon of intestinal submucosal arterioles (60-100 µ in diameter) were studied in male Wistar rats. Colloidal carbon particles diluted with distilled water were perfused through a catheter inserted into the common carotid artery; perfusion time was 15-20 min with 30-40 drops/min. The ultrastructure of normal submucosal intestinal arterioles in the rat was qualitatively similar to structure previously described in other organs and other animals. The internal elastic lamina was a fenestrated membrane from 0.1-1.2 μ thick. The fenestrae measured 0.1-1.4 μ, and an average of 1 fenestra was observed/3-4 μ in cross-section of the arteriole. Endothelial protrusions penetrated the elastic lamina corresponding to the fenestrae. In some cases the endothelial protrusions formed myoendothelial junctions. Interendothelial junctions were frequently localized in the endothelial protrusions. The arteriolar wall was not permeable to colloid carbon either as an active transfer or as a passive movement through the endothelium.

8174 HYDROLYSIS AND ABSORPTION OF PROLINE DIPEPTIDES ACROSS THE WALL OF SACS PREPARED FROM EVERTED RAT INTESTINE. *(E.)* Saidel, L. J.; Edelstein, I. (Chicago Med. Sch., Ill.). *Biochim. Biophys. Acta* 367(1):75-80, 1974.

Transfer of intact glycyl-L-proline, L-prolylglycine, L-prolyl-L-proline, L-leucyl-L-proline, L-prolyl-L-hydroxyproline, and *N*-formyl-L-leucine to the interior of sacs prepared from 5-cm segments of everted rat intestine was observed. The amounts varied from 0.24 ± 0.15 μM/30 min for leucylproline to 2.54 ± 0.23 μM/30 min for prolylproline. Of the 2 dipeptides containing glycine and proline, there was significantly more transfer of prolylglycine than of glycylproline. For most of the compounds examined, an inverse relation was found between the intact dipeptide or *N*-formylleucine transferred in 30 min and the total hydrolysis in the same period.

8208 DENERVATION POTENTIALS IN THE CANINE ESOPHAGUS. *(E.)*

Pelemans, W.; Van Trappen, G.; Hellemans, J.; Valembois, P.; Janssens, J. (Lab. Gastrointest. Pathophysiol., Univ. Louvain, Belgium). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 613-621.

The electromyographic pattern of the esophagus was studied in 9 dogs which had undergone unilateral medio-cervical vagotomy. Two of these dogs were also studied during thoracotomy. The recordings were compared to control recordings made in denervated gastrocnemius muscle. Before, and for the first 11 days after vagotomy, the esophagus was electrically silent. Activity returned after 12 days and was characterized by short spike potentials (± 2 msec) occurring in a regular rhythm and lasting for at least 5 months. This electromyographic activity was detected over the entire length and circumference of the thoracic and lower cervical esophagus and did not disappear following administration of curare (0.5-10 mg pancuronium bromide, i.v.). A second type of resting activity, characterized by positive sharp waves, was also observed rarely for the first few months following vagotomy but was gradually replaced by polyphasic potentials. Comparison of the experimental and control tracings suggests that unilateral cervical vagotomy produces a typical denervation pattern with fibrillation patterns and positive sharp waves. The appearance of polyphasic potentials later suggests that the esophagus is re-innervated.

8209 THE EFFECT OF VASOPRESSIN ON RESTING GASTROESOPHAGEAL SPHINCTER PRESSURE IN MAN. *(E.)*

Boesby, S.; Pedersen, S. A. (Odense Univ. Hosp., Denmark). *Scand. J. Gastroenterol.* 9(6):587-590, 1974.

The effect of exogenous vasopressin (50 μU/kg/min i.v. for 30 min) on resting lower esophageal sphincter pressure was studied in 13 normal human subjects. Mean sphincter pressure was significantly increased (from 14 mm Hg to 18 mm Hg) whereas mean fundic pressure remained unchanged (6 mm Hg). Following infusion, mean sphincter pressure returned to preinfusion values. These studies indicate that vasopressin is involved in the autoregulation of the gastrointestinal tract. The increase in lower esophageal sphincter pressure following vasopressin infusion is produced by a physiologic vasopressin dose, suggesting that this substance is an important component of both the physiologic and pathophysiologic regulation of the sphincter pressure.

8210 EFFECTS OF INCREASED INTRA-ABDOMINAL PRESSURE ON ESOPHAGEAL PERISTALSIS. *(E.)*

Dodds, W. J.; Hogan, W. J.; Stewart, E. T.; Stef, J. J.; Arndorfer, R. C. (Med. Coll. Wisconsin, Milwaukee). *J. Appl. Physiol.* 37(3):378-383, 1974.

The effect of increased intra-abdominal pressure on esophageal peristaltic function was studied in 18 volunteer subjects (average age 22.9 yr). Intraluminal pressure events were recorded using an infused catheter system and a strain gauge pressure probe. Abdominal compression by a pressure cuff in increments of 25 mm Hg caused 4-5 mm Hg incremental increases in intragastric pressure. Peristalsis was elicited by wet and dry swallows and recorded at abdominal compressions ranging from 0-75 mm Hg. When a bolus was present, graded increases in abdominal pressure caused progressive slowing of the peristaltic wave, increase in peristaltic complex duration, increase in pressure complex amplitude, and prolongation of lower esophageal sphincter relaxation. These changes occurred predominantly in the distal esophagus. Increased intra-abdominal pressure had no effect on peristalsis unaccompanied by an intraluminal bolus (i.e., dry swallow). The mechanism whereby increased intra-abdominal pressure causes quantitative changes in the variables of esophageal peristalsis during bolus transport may be determined by esophageal stretch reflexes, or the contractility characteristics of esophageal muscle, or both.

8211 SYMPATHETIC NERVE ACTIVITY DURING REFLEX SPINAL INHIBITION OF INTESTINAL MOTILITY.

(E.) Kelts, K. A.; Bignall, K. E. (Univ. Colorado Med. Ctr., Denver). *Am. J. Physiol.* 227(3):703-709, 1974.

The relation between mesenteric nerve activity and intestinal motility were examined during the intestinointestinal inhibitory reflex in the chloralose-urethan anesthetized cat. Distension of 1 jejunal loop by cannulation at both ends elicited a reflex inhibition of intestinal motility, recorded as an increase in intraluminal volume in another loop. Simultaneous increases in sympathetic nerve activity to the 2nd loop were detected, averaged, and integrated with a planimeter. Ganglionic blockade and splanchnicotomy abolished tonic efferent mesenteric nerve activity and augmented intestinal contractions, whereas vagotomy had no effect on either parameter. During an intestinointestinal inhibitory reflex, increases in sympathetic nerve activity and decrease in intestinal motility were directly related to the magnitude of the distending pressure and inversely to the prestimulus levels of nerve activity and intestinal tone. The magnitude of intestinal relaxation was directly related to the degree of increase in sympathetic activity. During maintained distension, sympathetic activity gradually decreased and, upon cessation of the stimulus, immediately fell below prestimulus levels. Blood flow in the mesenteric artery did not change significantly during the intestinointestinal inhibitory reflex. Tonic sympathetic inhibitory activity, maintained by mechanisms inherent in the intestinointestinal inhibitory reflex, may function as a constant restraint on intrinsically mediated peristaltic contractions that occur without demonstrable tonic vagal excitation.

8212 ACTION OF 5-HYDROXYTRYPTAMINE ON ELECTRICAL ACTIVITY OF AUERBACH'S PLEXUS IN THE ILEUM OF THE MORPHINE DEPENDENT GUINEA PIG. *(E.)* Takayanagi, I.; Sato, T.; Takagi, T. (Fac. Pharmacent. Sci., Univ. Tokyo, Japan). *Eur. J. Pharmacol.* 27(2):252-254, 1974.

Studies were conducted to determine the effects of 5-hydroxytryptamine (10^{-7}, 3 X 10^{-7} and 10^{-6} gm/ml), nicotine (10^{-6}, 3 X 10^{-6} and 10^{-5} gm/ml) and cerulein (10^{-9}, 3 X 10^{-9} and 10^{-8} gm/ml) on the electrical potential of Auerbach's plexus preparations from the ileum of guinea pigs made dependent on morphine by daily s.c. injections. Spontaneous spike frequencies of Auerbach's plexus from animals sacrificed 30-40 hr after the last dose of morphine ("abstinence syndrome") were faster than, although not significantly different from, those from animals which had received morphine 30 min before sacrifice or those from untreated controls. Random application of 5-hydroxytryptamine, nicotine or cerulein to Auerbach's plexus from control, morphine-treated or abstinence syndrome animals produced a dose-dependent increase in spike frequency. The Auerbach's plexus from guinea pigs with abstinence syndrome was particularly sensitive to 5-hydroxytryptamine, being about 10 times more so than the plexus from treated and control animals. These results suggest that morphine withdrawal excites the 5-hydroxytryptamine M-receptors in Auerbach's plexus and that this excitation accelerates liberation of acetylcholine from the nerves to increase spontaneous movement of the ileum.

8213 THE EFFECT OF STIMULATION ON THE MYOELECTRICAL ACTIVITY OF THE RECTOSIGMOID IN MAN. *(E.)* Taylor, I.; Duthie, H. L.; Smallwood, R.; Brown, B. H.; Linkens, D. (Dept. Surg., Univ. Sheffield, England). *Gut* 15(8):599-607, 1974.

To investigate the myoelectrical activity of the rectosigmoid *in vivo*, 66 subjects were studied at rest and after stimulation with either pentagastrin (6.0 μg/kg/hr i.v.) in 21 cases, neostigmine (0.5 mg i.m.) in 20 cases, or 2 bisacodyl suppositories in 19 cases. Three distinct myoelectrical states were distinguished: 1) a faster electrical rhythm with a frequency of 6-9 cycles/min; 2) a slower rhythm, frequency 2.5-4 cycles/min; and 3) stretches of electrical silence in which no obvious slow wave activity is seen. This state of inactivity predominated above the lower rectum. Of the 2 rhythms, the faster predominated and its incidence was significantly increased by neostigmine at all levels in the rectosigmoid and by bisacodyl in the rectum only. The incidence of the slower rhythm was significantly increased by pentagastrin which had no effect on the faster rhythm. The amplitude of each basic electrical rhythm rose when its incidence was increased. Motor waves were augmented corresponding to which of the 2 electrical rhythms was increased after stimulation.

SECRETION AND METABOLISM

8256 LINGUAL LIPASE. *(E.)* Hamosh, M.; Scow, R. O. (Natl. Inst. Arthritis, Metab., Dig. Dis., Bethesda, Md.). *4th Symp. Oral Secretion Perception. Development in the Fetus and Infant.* pp. 311-320, 1973.

Lipolytic activity in tissue homogenates, saliva and gastric contents was measured in tissue from adult female and 3-6 day old suckling rats. A high lipolytic activity was found in the serous glands of the tongue. The enzyme hydrolyzed triglyceride to mostly diglyceride and free fatty acids at a pH of 4.5-5.5. The activity was present in the tongue 2 days before birth and increased markedly after birth. The anterior oral pharyngeal wall, lateral oral pharyngeal wall, and soft palate also contained lipolytic activity but at a much lower level. Lipolytic activity was found in saliva collected through an esophageal cannula and in stomach contents of rats fed a fat-rich meal, as well as in the stomach contents of suckling rats. There was very little activity in the stomach, however, when saliva was excluded. Lipolytic activity was not present in gastric mucosa or in the large salivary glands. The findings suggest that the serous glands of the tongue secrete a potent lipase which acts in the stomach to hydrolyze dietary triglyceride to partial glycerides and free fatty acids. It is proposed that this reaction is the 1st step in the digestion of dietary lipid.

SECRETION AND METABOLISM

Stomach

8265 GASTRIC ACID SECRETION IN CONSCIOUS MINIATURE PIGS. *(E.)* Moeller, H.; Sewing, K. F.; Geisbe, H.; Schmolke, M. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 283(1):83-92, 1974.

Gastric acid secretion was studied in 5 miniature female pigs surgically provided with a chronic gastric fistula 5 weeks earlier. Basal secretion did not change significantly with age. Histamine (3.9-500 μg/kg), carbachol (1.6-200 μg/kg) or pentagastrin (0.25-32 μg/kg) produced a dose-dependent secretion volume and acid response with the highest peak acid output being achieved by histamine (30.1 ± 2.2 mEq H^+/hr). Maximal peak volume output following histamine was exceeded only by that following carbachol administration, the latter being due to excessive salivation.

8266 THE ACID-BASE BALANCE IN GASTRIC H^+ SECRETION. *(E.)* Russell, J. C.; Kowalewski, K. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Physiol. Chem. Phys.* 6(3):269-274, 1974.

The relations between the rate of hydrogen ion secretion and base excess in the blood, and between total carbon dioxide change and oxygen consumption were investigated in the canine stomach. *Ex vivo* stomachs from 24 dogs, isolated and perfused with homologous blood, were used for 234 thirty-min observations of the hydrogen ion secretion and corresponding blood acid-base oxygen status. The hydrogen ion secretion rate was found to be offset fairly precisely by arteriovenous increase in the base excess. The total carbon dioxide content of the venous blood was found to exceed that of the arterial blood by an amount much greater than the metabolic contribution through oxygen consumption. The data were fitted by the regression equation:

Δ_{total} CO_2 (mEq/min) = $-0.235 + 1.61 \times \Delta O_2$ (mM/min). The results indicate that the resting canine stomach removes carbon dioxide from the blood stream and subsequently releases it as a buffering agent during active hydrogen ion secretion.

8267 ANTRAL ACIDIFICATION AND THE GASTRIC SECRETORY RESPONSE TO PENTAGASTRIN AND ACETYLCHOLINE IN DOGS. *(E.)* Wheeler, M. H.; Prescott, R. J.; Forrest, A. P. M. (Dept. Clin. Surg., Univ. Edinburgh, Scotland). *Br. J. Surg.* 61(8):605-610, 1974.

In 6 dogs with innervated antral pouches (3 with vagally innervated fundic pouches and 3 with vagally denervated fundic pouches) gastric secretion was stimulated by submaximal doses of pentagastrin (0.125 to 1.0 μg/kg), each infused i.v. for a period of 6 hr. During the 3 consecutive 2-hr collection periods of each test the antral pouch was perfused with isotonic saline of pH 7.0, 1.0, and 7.0, resp., at 1 ml/min. Neither acid nor pepsin secretion was inhibited by antral acidification. When the antral perfusion rate was increased to 3 ml/min there was still no inhibition of acid secretion from either type of fundic pouch. In each dog the acid response of the fundic pouch to perfusion of the innervated antral pouch with 0.5% acetylcholine was significantly reduced when the pH of the perfusate was lowered from 7.0 to 1.0. The results provide no support for the existence of either an antral inhibitory hormone or inhibitory neural reflex active against pentagastrin-stimulated gastric secretion in the dog. It would seem that antral inhibition of gastric secretion is the result of a diminished release or formation of endogenous gastrin.

8268 THE ROLE OF VAGAL INNERVATION IN GASTRIC AND PANCREATIC RESPONSES TO MEALS VARYING IN pH. *(E.)* Dembinski, A.; Konturek, S. J.; Thor, P. (Med. Acad., Krakow, Poland). *J. Physiol. (Lond.)* 241(3):677-688, 1974.

In 3 dogs surgically provided with chronic gastric and pancreatic fistulas, gastric acid response to a 10% peptone meal was measured by a method of intragastric titration at pre-selected pH values from 6.0 to 2.0 or at a constant pH during i.v. infusion of secretin in graded doses from 0.25 to 4.0 U/kg/hr. Simultaneously, pancreatic secretion was determined by the standard collection technique and serum gastrin response was measured by radioimmunoassay. In this way the pH profile for the inhibition of gastric response and stimulation of pancreatic secretion as well as serum gastrin response to a peptone meal were determined and compared with that obtained with exogenous secretin or feeding a liver meal. Truncal vagotomy resulted in a significant 35% decrease of gastric acid response to the meal at all pH levels or at all doses of secretin, but the inhibitory effect of gastric acidification or secretin on serum gastrin and gastric acid response to a meal remained unchanged. Vagotomy caused a significant decrease in both pancreatic bicarbonate (40%) and protein (25%) output in response to meals at all pH levels and at all doses of secretin except the largest one. Pancreatic secretion stimulated by secretin alone was not affected by vagotomy, whereas that induced by feeding a liver meal was markedly decreased by this procedure. From these studies it was tentatively concluded that the vagus nerve facilitates the release of intestinal hormones and that vagotomy causes a decrease of gastric and pancreatic responses to endogenous but not to exogenous stimuli.

8269 GASTRIC SECRETORY RESPONSE TO ACUTE ISOTONIC HYPERVOLEMIA. *(E.)* Kraft, A. R.; Coran, A. G.; Homer, L. D.; Herman, C. M. (Natl. Naval Med. Ctr., Bethesda, Md.). *Am. J. Surg.* 128(5):624-627, 1974.

The effects of acute isotonic extracellular fluid volume expansion were studied in conditioned, anesthetized dogs who underwent pyloric ligation and creation of an external gastric fistula. A hypervolemic state was produced with i.v. Ringer's lactate solution (total fluid input of about 4 liters). The canine stomach responded as a "third-kidney" by significantly increasing gastric juice volume (528%) and gastric acid output (696%). This occurred paradoxically in the presence of a lactate load and a metabolic alkalosis. Vital signs and central venous pressure remained stable. Urinary output increased about 25-fold while the hematocrit fell by 20%. Thus, although the stomach may respond as a "third kidney" to isotonic hypervolemia, it apparently does so at the expense of acid-base homeostasis.

8270 EFFECT OF GLUCAGON ON PENTAGASTRIN-INDUCED GASTRIC SECRETION OF SODIUM, POTASSIUM AND CALCIUM IN MAN. *(E.)* Christiansen, J.; Hendel, L. (Glostrup Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(5):437-440, 1974.

The effect of glucagon on gastric secretion of sodium, potassium, and calcium was studied in 7 healthy individuals. Glucagon (20 μg/kg/hr) was administered as a continuous i.v. infusion on a background infusion of pentagastrin (1 μg/kg/hr). Secretory volume was decreased 42% during combined glucagon-pentagastrin infusion compared to infusion of pentagastrin alone. Gastric acid secretion followed a similar pattern, being inhibited 45% during combined infusion. Sodium output was reduced by 31%, but the ratio Na concentration/secretory rate increased by 26%, indicating a relative increase in sodium output. Potassium secretion was inhibited by 57%. Calcium concentration increased slightly (13%), and output was inhibited to the same degree as volume secretion (48%).

8271 IMPLICATION OF GASTRIC MUCOSAL HISTAMINE IN INHIBITION BY ISOPRENALINE OF PENTAGASTRIN-INDUCED GASTRIC SECRETION. *(E.)* Lundell, L.; Svensson, S. E. (Inst. Physiol., Univ. Lund, Sweden). *Br. J. Pharmacol.* 52(1):69-75, 1974.

The effect of isoprenaline (20-40 µg/kg/hr i.v.) on pentagastrin-induced release and formation of gastric mucosal histamine as well as on pentagastrin-induced gastric secretion was studied in female Sprague-Dawley rats fed a standard diet. Isoprenaline strongly inhibited pentagastrin-induced acid secretion, an inhibition which could not be overcome by increasing the dose of pentagastrin from 0.25 µg/hr to 16 µg/hr. Propranolol (2 mg/kg) blocked the inhibitory effect of isoprenaline on pentagastrin-induced acid secretion. Isoprenaline enhanced pepsin secretion induced by pentagastrin, an effect which was blocked by propranolol. It also reduced the increase in formation and release of gastric mucosal histamine following pentagastrin infusion, an inhibitory influence which was almost completely blocked by propranolol. The inhibition by isoprenaline of pentagastrin-induced acid secretion is tentatively related to alterations in gastric mucosal histamine occurring simultaneously.

8272 EFFECT OF H_2 RECEPTOR ANTAGONISTS ON HISTIDINE DECARBOXYLASE ACTIVITY IN RAT GASTRIC MUCOSA. *(E.)* Maudsley, D. V.; Kobayashi, Y.; Bouvaird, L.; Zeidel, M. (Worcester Fdn. Exp. Biol., Shrewsbury, Mass.). *Biochem. Pharmacol.* 23(21): 2963-2968, 1974.

The effects of the H_2 receptor antagonists, burimamide (50 mg/kg) and metiamide (25 mg/kg), on increasing histidine decarboxylase activity in the glandular stomach of female Charles River rats were studied. The drugs were given i.p. to 24 hr-starved animals. Tissue was removed at various times up to 6 hr thereafter and assayed for histidine decarboxylase activity. The increase in enzyme activity was reduced by cycloheximide (10 mg/kg) but not by actinomycin D (1 mg/kg). An inhibitor of histidine decarboxylase, 4-imidazolyl-3-amino-2-butanone (MeN-A-1293) was also effective in reducing the enzyme activity stimulated by the H_2 receptor antagonists. The time course and the magnitude of the response of the enzyme with maximum doses of burimamide were similar to those obtained with pentagastrin. The histamine content of the mucosa was also reduced by burimamide. These data are consistent with the hypothesis that H_2 receptor antagonists increase histidine decarboxylase activity by raising gastric pH and causing release of endogenous gastrin.

8273 HYDROCORTISONE ADMINISTRATION AND GASTRIN AND GASTRIC SECRETION IN DOGS. *(E.)* Watson, L. C.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Arch. Surg.* 109(4): 547-549, 1974.

Studies were undertaken in dogs to test the acute effect of administration of hydrocortisone (50, 100, 150 mg i.v. at 45 min intervals) and daily injection (100 mg/day for 5 days), on serum gastrin levels. Acute administration of hydrocortisone had no appreciable effect on serum gastrin levels: the mean basal concentration of 72 ± 3 pg/ml did not change significantly after the steroid infusions. Subacute administration produced a significant (20%) increase in serum gastrin (from 98 ± 5 pg/ml before hydrocortisone to 121 ± 7 pg/ml after treatment); as well as in serum gastrin response to a traditional meat meal (from 10.2 ± 2 ng-min/ml in the control study to 16.1 ± 3 ng-min/ml in the posthydrocortisone study). The increased serum gastrin levels following hydrocortisone administration were accompanied by a 100% increase in gastric acid output as determined by standard titration techniques. These findings suggest that at least 1 of the mechanisms of formation of steroid-induced ulcers is their effect on the hormonal mechanism leading to increased gastric acid levels.

8274 DIFFERENTIAL EFFECTS OF SALMON, PORCINE, AND HUMAN CALCITONIN ON GASTRIC SECRETION AND GASTRIC EMPTYING IN RATS. *(E.)* Bobalik, G. R.; Kleszynski, R. R.; Aldred, J. P.; Bastian, J. W. (Armour Pharmaceut. Co., Kankakee, Ill.). *Proc. Soc. Exp. Biol. Med.* 147(1):284-288, 1974.

The effects of porcine, salmon and human calcitonin were studied on gastric acid secretion in rats subjected to pyloric ligation, and on gastric emptying in normal rats. All animals were starved for 24 hr prior to the experiment. Calcitonin from all 3 sources at concentrations from 0.5-8.0 U/kg injected s.c. produced a dose-dependent inhibition of gastric acid secretion as well as a delay in gastric emptying time determined following ingestion of a meal containing Evan's blue dye. When standardized on the basis of their hypocalcemic potencies, human calcitonin was considerably less effective than either salmon or porcine calcitonin. Relative potencies were 0.06, 0.80 ± 0.63 and 1.00, resp., for acid secretion and 0.04 ± 0.02, 0.91 ± 0.13 and 1.00, resp., for gastric emptying. Thus, these effects are not mediated by changes in serum calcium.

8275 SECRETORY FUNCTION OF TOTALLY ISOLATED PORCINE STOMACH PERFUSED EX VIVO WITH HOMOLOGOUS BLOOD: EFFECT OF HISTAMINE. *(E.)* Kowalewski, K.; Secord, D. C.; Kolodej, A. (Univ. Alberta, Edmonton, Canada). *Can. J. Surg.* 17(5): 340-347, 1974.

A method of isolation and *ex vivo* perfusion of the whole porcine stomach is described. The stomach was perfused extracorporeally with homologous blood of a supporting pig which served as a living oxygenator and dialyzer. Histamine (150 µg/hr) given by intraarterial infusion was used as a secretagogue.

Samples of gastric juice and blood were collected every 30 min during the perfusion period for analysis. All porcine stomachs secreted H$^+$ and pepsin. The results demonstrated that *ex vivo* porcine stomachs secreted about 1/3 of the volume and acid but about five times more pepsin than did canine stomachs in similar situations. This new experimental tool appears to be adequate for the study of gastric secretory function of the porcine stomach.

8276 ALTERATIONS IN HISTAMINE METABOLISM OF RAT GASTRIC MUCOSA FOLLOWING VAGOTOMY. *(E.)* Lundell, L.; Rosengren, E.; Svensson, S. E. (Inst. Physiol., Univ. Lund, Sweden). *J. Physiol. (Lond.)* 242(1):209-218, 1974.

The effects of truncal vagotomy plus pyloroplasty alone, or sham operation on the formation of gastric mucosal and whole body histamine were determined in female Sprague-Dawley rats fed a histamine-free diet. Following truncal vagotomy with pyloroplasty, mucosal histamine formation determined *in vitro* increased by 5-fold and was associated with elevated mucosal histamine levels and an enhanced urinary histamine excretion. Infusion of i.v. pentagastrin (8 µg/hr) produced a 2-fold increase in mucosal histamine formation following vagotomy and pyloroplasty and a 7-fold increase in sham-operated controls. Mucosal histamine content in both groups subsequently fell over a 3-hr period to comparable levels during which time urinary histamine excretion was appropriately enhanced. In studies where ^{14}C-histidine was injected and urinary ^{14}C-histamine was subsequently measured, newly synthesized histamine was more slowly mobilized during the first hr of pentagastrin infusion following vagotomy and pyloroplasty than following sham operation. Rats subjected only to pyloroplasty and infused with pentagastrin showed a significantly higher increase in urinary histamine than did the sham operated controls. Kinetic studies using ^{14}C-histidine showed that this was probably due to a preferential mobilization of preformed intracellular histamine.

8277 HISTAMINE METABOLISM OF THE GASTRIC MUCOSA FOLLOWING ANTRECTOMY. *(E.)* Lundell, L. (Inst. Physiol., Univ. Lund, Sweden). *J. Physiol. (Lond.)* 241(2):437-451, 1974.

Mucosal histamine metabolism was studied in female Sprague-Dawley rats maintained on a histamine-free diet and subjected to antrectomy, antrum exclusion, or total gastrectomy with or without subsequent i.v. pentagastrin substitution (8 µg/hr). Antrectomy resulted in approximately a 67% decrease in gastric mucosal histamine formation as determined by biochemical assay, whereas antrum exclusion produced a more than a 2.5-fold increase. Mucosal histamine content also decreased after antrectomy and increased following antrum exclusion. Whole body histamine formation, as determined from the rate of urinary histamine excretion, was decreased by 50% following total gastrectomy. Pentagastrin infusion failed to increase histamine excretion, as it did in animals with intact stomachs, indicating that histamine was not mobilized from extra-gastric sources. Determination of the rate of urinary excretion of ^{14}C-histidine showed that histamine was mobilized initially to a larger extent in pentagastrin infused antrectomized animals than in control rats. Studies of the rate of histamine excretion in antrectomized rats supplemented with daily pentagastrin injections showed that after 3 weeks, histamine excretion was 1.5-fold higher than in the nonsubstituted group, but was the same after 6 weeks. Pentagastrin was less effective in elevating mucosal histamine formation in nonsubstituted antrectomized rats than in the substituted and sham operated animals. These results emphasize the predominant role of antral gastrin in sustaining mucosal histamine formation as well as the responsiveness of histidine decarboxylase to stimulation by pentagastrin or gastrin.

SECRETION AND METABOLISM

Hepatobiliary Tract

8313 LONG-TERM PERFUSION OF THE ISOLATED RAT LIVER. MAINTENANCE OF ITS FUNCTIONAL STATE BY USE OF A FLUOROCARBON EMULSION. *(E.)* Krone, W.; Huttner, W. B.; Kampf, S. C.; Rittich, B.; Seitz, H. J.; Tarnowski, W. (Inst. Physiol. Chem., Univ. Hamburg, Germany). *Biochim. Biophys. Acta* 372(1):55-71, 1974.

A fluorocarbon emulsion containing liquid fluorocarbon 43 made up in the nonionic detergent Pluronic F 68 by sonication and diluted with a saline buffer was tested as a long-term perfusion system for periods up to 20 hr in the isolated male Wistar rat liver. All livers perfused with the fluorocarbon medium released phosphoglucose isomerase, glutamate-oxaloacetate transaminase, and glutamate dehydrogenase almost linearly at a low basal rate, glutamate dehydrogenase release beginning after 5 hr perfusion. In contrast, a certain percentage of the livers perfused with a red cell-containing medium showed an exponential enzyme release which was over two standard deviations above the mean of the livers perfused with the fluorocarbon mixture, the values being 25% for phosphoglucose isomerase, 38% for glutamate-oxaloacetate transaminase, and 87% for glutamate dehydrogenase after 10 hr of perfusion. Liver functions examined in fluorocarbon-perfused and red cell-perfused livers during a 10 hr period were metabolite state, galactose elimination from the perfusate, induction of tyrosine aminotransferase by dexamethasone, and gluconeogenesis from lactate and bile production. The fluorocarbon medium provided at least the same or an even better hepatic function than did the red cell-containing medium. However, while in red cell-perfused livers functional impairment always occurred at various percentages, this was never observed with the fluorocarbon medium. Electron microscopic examination of the livers perfused with the fluorocarbon medium showed no disturbance of the mitochondrial matrix and cristae after a 10 hr perfusion.

8314 LIPOPROTEINS IN A NONRECIRCULATING PERFUSATE OF RAT LIVER. *(E.)* Marsh, J. B. (Sch. Dent. Med., Univ. Pennsylvania, Philadelphia). *J. Lipid Res.* 15(6):544-550, 1974.

Rat (male Holtzman, 250-400 g) livers were perfused in a nonrecirculating system for 30-40 min with Krebs-Ringer bicarbonate-0.1% glucose solution gassed with 95% O_2-5% CO_2 at 37 C at a flow rate of 3 ml/g/min. The livers appeared normal as judged by O_2 uptake, bile flow, transaminase release, and net protein output (2.5 mg/g/hr). The perfusate was concentrated by ultrafiltration, subjected to sequential ultracentrifugation at solution densities of 1.006, 1.04, 1.06, and 1.21, and the top fractions analyzed for protein and lipid. The net release of protein in the 4 density classes, averaged 39, 10, 5 and 20 μg/g/hr. The lipid composition of the perfusate lipoprotein fractions differed from that of serum mainly in the high percentage of free cholesterol. It is concluded that the rat liver secretes very low-density lipoprotein (VLDL), high-density lipoprotein (HDL), and a modified form of VLDL containing less lipid. Comparison of secretion rates and serum lipoprotein levels leads to the conclusion that the latter are largely determined by catabolic rates. When labeled amino acids were present, the perfusate HDL had a higher specific activity than VLDL. Addition of carrier whole serum did not alter recovery of labeled lipoproteins, but when these were isolated from Golgi membranes after a 40-min perfusion, more than twice as much label was recovered in HDL, suggesting the presence of precursors within the Golgi. The main advantages of the nonrecirculation perfusion technique are the avoidance of catabolic reactions, simplicity, and complete control over the composition of the perfusing medium.

8315 ESTIMATION OF FUNCTIONAL HEPATIC MASS IN RESECTED AND REGENERATING RAT LIVER. *(E.)* Rikkers, L. F.; Moody, F. G. (Univ. Utah Med. Ctr., Salt Lake City). *Gastroenterology* 67(4):691-699, 1974.

The kinetics of indocyanine green (ICG) removal by control, partially resected, and regenerating male Sprague-Dawley rat livers were studied to test the hypothesis that its maximal rate of removal is a reliable measure of hepatic functional mass. ICG analysis was performed in a total of 200 rats, only 9 of which were not included in the final data computation. Hepatic uptake of ICG administered in incremental doses followed Michaelis-Menten kinetics, thereby providing a means of calculating maximal rate of uptake (R_{max}) from removal rates of sub-maximal doses. Decrease in hepatic mass by weight after 35 and 65% hepatectomy could be identified with a reasonable degree of accuracy by determination of R_{max}. R_{max} closely correlated with return of liver weight during hepatic regeneration. Serum bilirubin, alkaline phosphatase, albumin, and transaminase were not related to liver weight. Temperature had a profound effect on ICG uptake with hyperthermia causing a reduction in R_{max}. Under these experimental conditions, estimation of maximal removal rate for ICG provided a relatively reliable (about ± 10%) method of quantitating hepatic mass.

8316 MEASUREMENT OF PROTEIN TURNOVER IN RAT LIVER WITH [^{14}C]CARBONATE: PROTEIN TURNOVER DURING LIVER REGENERATION. *(E.)* Swick, R. W.; Ip, M. M. (Dept. Nutr. Sci., Univ. Wisconsin, Madison). *J. Biol. Chem.* 249(21):6836-6841, 1974.

Several isotopic methods for measuring liver protein turnover were compared in a study of plasma albumin and the mixed hepatic proteins during liver regeneration in young Holtzman rats. In albumin after i.v. or i.p. administration of ^{14}C-carbonate (1 mC), the rate of decay of the radioactivity of the intact protein was similar to that of arginine isolated from the protein, whereas after the administration of guanidino-^{14}C-arginine (45 μC), the decay rate was 30% slower than that obtained with ^{14}C-carbonate. When guanidino-^{14}C-arginine is given, the extrahepatic tissues, such as muscle, and the plasma globulins, are labeled more heavily than the liver proteins. The reutilization of this extrahepatic arginine by the liver probably accounts for the slower disappearance of radioactivity from albumin. Similar results were obtained with the mixed, indigenous hepatic proteins. In partially hepatectomized animals, the decay in radioactivity in arginine after ^{14}C-carbonate administration showed that the rate of protein breakdown was reduced by 30% during the first 5 days of liver regeneration. There was no decay in radioactivity in similar animals given guanidino-^{14}C-arginine, suggesting a massive transfer of labeled extrahepatic protein arginine into the liver during regeneration.

8317 VALIDITY OF USING 2,4-^{3}H-LABELED BILE ACIDS TO STUDY BILE ACID KINETICS IN MAN. *(E.)* LaRusso, N. F.; Hoffman, N. E.; Hofmann, A. F. (Mayo Clin., Rochester, Minn.). *J. Lab. Clin. Med.* 84(5):759-765, 1974.

[2,2',4,4'-^{3}H]Chenodeoxycholic acid was administered i.v. simultaneously with [24-^{14}C]chenodeoxycholic acid to 2 healthy subjects, and the ^{3}H/^{14}C ratio in bile samples was measured daily for 6 days by liquid scintillation spectroscopy. This ratio remained identical to that administered, indicating stability of the label. Approximately 12% of administered ^{3}H entered body water and 5-10% was excreted in the urine as $^{3}H_2O$ in 6 days. In similar studies with [2,2',4,4'-^{3}H]cholic acid and [24-^{14}C]-cholic acid in 3 subjects, biliary cholic acid and deoxycholic acid were isolated chromatographically and the ^{3}H/^{14}C ratio of each bile acid was determined. For cholic acid, about 10% of administered ^{3}H was lost the 1st day; after that, the ^{3}H/^{14}C ratio remained constant. In deoxycholic acid, the ^{3}H/^{14}C ratio was 30-40% lower than in that administered. Approximately 25% of administered ^{3}H entered body water and 8% was excreted in the urine as $^{3}H_2O$ in 6 days. On anaerobic incubation of [2,4-^{3}H] cholic and [2,4-^{3}H] chenodeoxycholic acids with fresh feces, 20-35% of the label was released as $^{3}H_2O$. Seven of 24 strains of bacteria tested were capable of releasing ^{3}H as $^{3}H_2O$ when incubated anaerobically with [2,4-^{3}H]cholic acid, but the fraction ^{3}H released was much less than that during fecal incubation. Determination of bile acid kinetics in healthy subjects is valid with [2,2',4,4'-^{3}H]-chenodeoxycholic acid and has an error of $<$ 10% with [2,2',4,4'-^{3}H]cholic acid. However, the 2,2',4,4'-^{3}H label appears unsatisfactory for tracing the complete metabolic fate of the steroid moiety of bile acids in healthy man because ^{3}H is removed by bacteria during intestinal passage after the labeled bile acids leave the exchangeable bile acid pool.

8318 DISTRIBUTION OF LIVER PLASMA MEMBRANE 5' NUCLEOTIDASE AS INDICATED BY ITS REACTION WITH ANTI-PLASMA MEMBRANE SERUM.

(E.) Gurd, J. W.; Evans, W. H. (Natl. Inst. Med. Res., London, England). *Arch. Biochem. Biophys.* 164(1):305-311, 1974.

Antisera, highly specific for mouse liver surface membranes was produced to investigate the properties of 5' nucleotidase (5'N). Purified mouse liver surface membranes (50 μg, 1 U 5' AMPase) were preincubated for 60 min at room temperature with increasing amounts of antisera. The result was a progressive inhibition of 5'N activity until a maximal inhibition of 80-90% was attained. Nonimmune serum and antiserum preabsorbed with the plasma-membrane fraction possessed no inhibitory activity. Purified 5'N (0.4 U) and phosphodiesterase (0.25 U) were incubated with immune γ-globulin for 60 min at room temperature followed by 18 hr at 4 C prior to the determination of enzyme activity. Purified 5'N was completely sensitive to antibody inhibition but phosphodiesterase activity was unaffected. The preincubated surface membranes also failed to inhibit nucleotide pyrophosphatase or insulin binding. Membrane bound 5'N and purified enzyme (0.4 U) were incubated separately with sufficient amount of antiserum to produce approximately 50% inhibition. Inhibition curves from both enzymes were similar and of the noncompetitive type. The inhibitory effect of antiserum (1-50 μl) on 5'N activity present in light (120 μg), and heavy (250 μg) plasma membrane fractions was determined and both fractions were equally sensitive to the antibody. Anti-mouse liver plasma membrane antiserum on 5'N activity of mouse liver (25 μg), rat liver (75 μg), and pig lymphocyte (75 μg) surface membranes showed that the enzymatic activity in each of these membranes was inhibited to a similar extent. The reaction of an antibody with a membrane bound enzyme is evidence that the portion of the protein containing the antigenic site is exposed on the membrane surface. These results are consistent with the studies which indicated that 5'N was located on the outer surface of the plasma membrane lining the bile space, and also with the findings that the enzyme is a glycoprotein.

8319 DEVELOPMENTAL CHANGES IN RAT LIVER XANTHINE OXIDASE(S) AND ITS INTRACELLULAR DISTRIBUTION.

(E.) Hashimoto, S. (Life Sci. Lab., Ajinomoto Co., Inc., Yokohama, Japan). *Agr. Biol. Chem.* 38(9):1697-1702, 1974.

Developmental changes and subcellular distribution of xanthine oxidase in the livers of male pre- and postnatal Wistar rats were examined. The rats were sacrificed by decapitation, the liver removed and homogenized, and the liver homogenate centrifuged at 100,000 X g for 60 min at 0 C. Xanthine oxidase activity was measured spectrophotometrically. The specific activity of the fetal liver xanthine oxidase increased sharply to the levels of the adult liver on the day of birth. After birth, the activity dropped rapidly until the 14th day after birth when it was about 1/4 that of the adult level. About the 28th day after birth, the activity had again risen to the level found on the day of birth. In the livers of 80 day-old rats, about 60% of the total xanthine oxidase activity was found in the soluble fraction and the rest was distributed among particulate fractions including microsomal, lysosomal, mitochondrial, and nuclear fractions. In contrast to the adult livers, 80% of total xanthine oxidase activity in fetal liver was found in particulate fractions. It is suggested that there may be two types of liver xanthine oxidase, one a fetal type, present mainly in the particulate fraction; and the other an adult type, present mainly in the soluble fraction.

8320 BIOSYNTHESIS OF LIPIDS IN GOLGI COMPLEX AND OTHER SUBCELLULAR FRACTIONS FROM RAT LIVER.

(E.) Van Golde, L. M. G.; Raben, J.; Batenburg, J. J.; Fleisher, B.; Zambrano, F.; Fleischer, S. (Lab. Vet. Biochem., State Univ. Utrecht, Netherlands). *Biochim. Biophys. Acta* 360(2):179-192, 1974.

Various subcellular fractions, including the Golgi apparatus, were isolated from rat liver and were assayed biochemically for the following: 1) synthesis of sphingomyelin, ceramide choline phosphotransferase (CDP) diglycerides, phosphatidylinositol and phosphatidylserine; 2) conversion of phosphatidylserine to phosphatidylethanolamine; 3) formation of lecithin *via* N-methylation; and 4) activation of palmitic and octanoic acids. Purity of the various subcellular fractions was assessed using specific marker enzymes. The principal site for synthesis of sphingomyelin, CDP diglycerides, phosphatidylinositol, phosphatidylserine, and lecithin is the endoplasmic reticulum. With the exception of CDP diglyceride synthesis, however, mitochondria possess none of these abilities, although the inner mitochondrial membrane is the only cellular site of phosphatidylserine decarboxylation. Palmitate activation takes place primarily in the endoplasmic reticulum and the mitochondria although plasma membranes also possess a small amount of activity. The subcellular distribution of octanoyl-coenzyme A (CoA) synthetase is similar to that of palmitoyl-CoA synthetase, except that octanoyl CoA synthetase activity is greater in mitochondria than in microsomes.

8321 LIPID PEROXIDES AND THE INDUCTION OF HEPATIC MICROSOMAL CYTOCHROME P-450 IN THE RAT.

(E.) Marshall, W. J.; Naughton, C. (King's Coll. Hosp. Med. Sch., London, England). *Biochem. Soc. Trans.* 2(5):992-994, 1974.

The hypothesis that the induction of hepatic microsomal cytochrome P-450 is mediated through an endogenous inducer, and that this inducer is a lipid peroxide or some related substance, was investigated in male Wistar rats fed a standard laboratory diet. Microsomal fractions were prepared, the cytochrome P-450 was measured, and the peroxide content of liver homogenates was determined by an iodometric method. After a single injection of phenobarbital (100 mg/kg, i.p.), cytochrome P-450 concentrations were unchanged for 6 hr, slightly increased after 9 hr, and significantly increased after 12 hr. In contrast, peroxide concentration in the liver increased rapidly between 3 and 6 hr, giving a 5-fold increase over the initial value at 6 hr. A high concentration was maintained while cytochrome P-450 concentration was increasing, but by 72 hr peroxide concentration had returned to baseline values. These results support the suggestion that the induction of hepatic microsomal cytochrome P-450 is mediated through an endogenous lipid peroxide.

8322 VITAMIN E, STEROIDS, AND LIVER MICROSOMAL HYDROXYLATIONS.

(E.) Carpenter, M. P.; Howard, Jr., C. N. (Oklahoma Med. Res. Fdn., Oklahoma City). *Am. J. Clin. Nutr.* 27(9):966-979, 1974.

Drug metabolism, microsomal cytochromes, and lipid peroxidation by liver microsomes of control rats fed a vitamin E-supplemented diet, and of experimental rats fed a vitamin E-deficient diet were compared to determine whether the effect of α-tocopherol on microsomal oxidases is mediated *via* androgens, or is independent of these steroids. The animals used in the study were adult male albino rats derived from the Holtzman-Sprague-Dawley strain. Identical analyses were also made of control and experimental rats that were castrated, adrenalectomized, or both. Groups of rats in which steroid producing organs were surgically removed were treated with appropriate replacement steroids or α-tocopherol. To determine whether the effect of α-tocopherol on microsomal hydroxylations was similar to that of phenobarbital, induction by this drug was also studied in unoperated, castrated, adrenalectomized, and castrated-adrenalectomized rats. The specific activities were not decreased in vitamin E-supplemented animals after castration, unlike those of the vitamin E-deficient rats. Adrenalectomy resulted in a diminution in both groups. In the vitamin E-deficient rat the effect of castration could be reversed with α-tocopherol or testosterone. Corticosterone plus hydrocortisone partially restored activity in adrenalectomized controls and experimentals, and in the latter group vitamin E had the same effect. Steroid hormones were partially restored in controls and experimentals that had been castrated and adrenalectomized. These effects were also seen with tocopherol treatment of the double-operated experimentals. The effect of phenobarbital as an inducer was found to depend in part on the androgen status of the animals but part of the effect was independent of this factor. With regard to phenobarbital induction, the vitamin E-supplemented animal was less dependent on androgen than the deficient rat and the requirement for androgen in the experimental animal was replaced by tocopherol.

8323 HEPATIC BIOSYNTHESIS OF CHOLESTEROL IN MAN: NORMAL RANGE AND CHANGES INDUCED BY DRUGS.

(E.) Bamonti, F. (Gen. Reg. Hosp., Ancona, Italy). *Rend. Gastroenterol.* 5(3):220, 1973.

Studies were performed to evaluate the rate of hepatic cholesterol synthesis (HCS) in normal human liver and to investigate changes in HCS following treatment with drugs known to induce microsomal enzymes. The HCS was estimated with a few milligrams of tissue obtained by needle biopsy in 54 human subjects. Measurements were made of the incorporation of radiocarbon-labeled acetate into digitonin-precipitable sterols. The average rate of HCS in 19 normal subjects was 401 ± 119 nM/g/2 hr, while the average rate in 8 patients with extrahepatic cholestasis was 748 ± 300. Incorporation of labeled acetate into digitonin-precipitable sterols for 4 patients with steatosis and latent diabetes was in the normal range. Mean values of HCS in 12 subjects treated with diazepam were 2210 and 1225 nM/g, resp., after the 4th day of treatment and from 3-6 days after suspension of the drug. The average HCS value in 2 patients treated with phenobarbital was 935 nM/g on the 5th or 6th day of treatment, while in 5 other subjects it was 439 nM/g at 4-5 days after drug withdrawal. During therapy with prednisolone or with phenothiazine, the synthesis rate was 1089 nM/g (1 subject) and 477 nM/g (3 subjects), resp. All drugs were given at therapeutic doses. Changes in cholesterolemia were not observed. The results indicate that some drugs which induce microsomal enzymes of the hepatocyte may cause marked and unexpected clinically silent changes in cholesterol metabolism. The possibility of such undesirable effects must be taken into consideration, especially in long-term therapy.

8324 THE INDUCTION OF HEPATIC CHOLESTEROL SYNTHESIS IN THE RAT BY LECITHIN MESOPHASE INFUSIONS.

(E.) Jakoi, L; Quarfordt, S. H. (VA

Hosp., Durham, N.C.). *J. Biol. Chem.* 249(18):5840-5844, 1974.

Studies were conducted to determine the mechanism of the increased hepatic cholesterol synthesis observed in rats following infusion of lecithin mesophase dispersions. A 4-hour i.v. infusion of egg lecithin (20 mg/ml, 2.3 ml/hr) produced a 3- to 10-fold increase in hepatic cholesterol synthesis from acetate in both liver slices and homogenates. Direct *in vitro* additions of lecithin to the homogenates produced no change in the conversion of acetate to cholesterol. Mevalonate conversion to cholesterol in both homogenates and slices was unchanged by lecithin infusions. An increase of similar magnitude in the activity of the enzyme 3-hydroxy-3-methylglutaryl coenzyme A reductase was seen after the lecithin infusion. This increase in enzyme activity was associated with a significantly lower microsomal cholesterol content. The increase in cholesterol synthesis was prevented when the infused lecithin was made to molar ratios of cholesterol to lecithin greater than 0.5:1. Cholesterol-lecithin infusions with molar ratios of 1:1 appeared to inhibit conversion of acetate to cholesterol. The cholesterol content of the microsomes following these infusions was greater than control. Pretreatment of the animals with cycloheximide (0.5 mg/100 g) abolished the activation of cholesterol synthesis by lecithin, but actinomycin D (30 µg/100 g) had no effect. These results suggest that the accelerated hepatic cholesterol synthesis following lecithin infusion is a compensatory response to depletion of liver cholesterol levels and that mesophase infusion possibly influences translational control of regulatory enzyme production.

8325 TAUROCHOLATE EXCRETION AND BILE FORMATION IN THE ISOLATED PERFUSED RAT LIVER. AN IN VITRO-IN VIVO COMPARISON. *(E.)* Paumgartner, G.; Herz, R.; Sauter, K.; Schwarz, H. P. (Inst. Clin. Pharmacol., Univ. Bern, Switzerland). *Naunyn Schmiedebergs Arch. Pharmacol.* 285(2):165-174, 1974.

The excretory transport maximum (Tm) for taurocholate was determined in the perfused rat liver and compared to that obtained in the intact rat. An *in situ* liver perfusion system employing a semisynthetic perfusion medium containing Krebs-Ringer-bicarbonate solution, bovine erythrocytes, and bovine albumin was used in a total of 21 male Sprague-Dawley rats weighing 232-272 g. Total bile acids in bile were determined enzymatically using a 3α-hydroxysteroid dehydrogenase; mean recovery of sodium taurocholate added to bile was 98%. In contrast to the BSP-Tm, the taurocholate-Tm was 45% smaller *in vitro* (196 ± 17 nM/min/g liver) than *in vivo* (357 ± 10 nM/min/g liver), indicating that bile salt transport is more susceptible to alterations induced by the conditions of perfusion than BSP transport. At a low taurocholate infusion rate (57 nM/min/g liver) the normal relationship between bile salt excretion and bile flow observed *in vivo* was maintained in the perfused liver. At higher taurocholate infusion rates, however, bile flow, for a given bile salt excretion rate, was smaller than *in vivo*. Theoretically, a decrease of the osmotic activity of bile salts or an inhibition of bile salt independent bile formation could be responsible for this effect. Although the 1st possibility cannot be excluded, the 2nd appears more likely. These findings should be taken into account when the isolated perfused rat liver is employed for studies of bile formation.

8326 HEPATIC ACTION OF VASOPRESSIN: LACK OF A ROLE FOR ADENOSINE-3',5'-CYCLIC MONOPHOSPHATE. *(E.)* Kirk, C. J.; Hems, D. A. (Dept. Biochem., Imperial Coll. Sci. Technol., London, England). *FEBS Lett.* 47(1):128-131, 1974.

The effect of vasopressin on hepatocyte cyclic AMP levels was studied *in vivo* and *in vitro*. Cyclic AMP levels were measured by a radioisotope saturation assay in rat livers during a 30 min perfusion with a solution containing albumin, washed rat RBC, and glucagon (10 ng/ml), adrenalin (10^{-6} M) or vasopressin (100 mU/liter), and in acid insoluble extracts of livers from intact rats injected *via* the portal vein with glucagon (1.0 µg), adrenalin (1.5 X 10^{-8}M), or vasopressin (10 or 100 mU). In both intact rats and perfused liver, vasopressin failed to increase intracellular hepatocyte cyclic AMP concentration although in perfused liver it did cause increased glucose output of the same order of magnitude as that produced by adrenalin. In both systems, adrenalin and glucagon produced an increase in cyclic AMP. These results confirm the results of previous studies. The glycogenolytic action of vasopressin on the liver thus appears to be unique among hormones with short-term "catabolic" effects in that it is associated with no discernible alteration in tissue cyclic AMP concentration.

8327 INTERACTIONS OF PROSTAGLANDINS WITH HEPATIC MICROSOMAL CYTOCHROME P-450. *(E.)* Kupfer, D. (Worcester Fdn. Exp. Biol., Shrewsbury, Mass.). *Life Sci.* 15(4):657-670, 1974.

Studies were conducted to determine whether prostaglandins interact with the hepatic cytochrome P-450 system. To this end, the spectral changes associated with the addition of prostaglandins to hepatic microsome preparations from guinea pigs and rats were examined. Prostaglandins A_1, A_2, E_1, E_2, $F_{1\alpha}$ and $F_{2\alpha}$, when added to guinea pig liver microsomes, exhibited type I spectra (a trough at 420 nm and a peak at about 385 nm). The binding affinities as determined from spectral dissociation constants were highest with prostaglandins A_1 and A_2. With liver microsomes from control or 3-methylcholanthrene-treated rats, prostaglandins did not yield type I spectra; however, in this case a weak spectrum, designated as type "II" (λ_{max} at 415-425 nm and a weak but occasionally absent λ_{min} at 390-400 nm) was at times observed. With microsomes from phenobarbital-treated rats only prostaglandins A_1 and A_2 yielded type I spectra; again in absence of type I spectrum, a weak type "II" was occasionally observed. The addition of prostaglandins A_1 and A_2 to liver microsomes from phenobarbital-treated rats inhibited the microsomal mediated hydroxylation of hexobarbital. The inhibition by prostaglandin A_1 was competitive; the inhibitory constant (8.2 X 10^{-4} M) was found to be similiar in magnitude to the dissociation constant (7.3 X 10^{-4} M) of prostaglandin A_1 observed with rat liver microsomes. These observations suggested that prostaglandins, particularly of the A series, interact with the hepatic microsomal cytochrome P-450 monoxygenase system.

8328 THYROID HORMONE ACTION. IN VITRO CHARACTERIZATION OF SOLUBILIZED NUCLEAR RECEPTORS FROM RAT LIVER AND CULTURED GH_1 CELLS. *(E.)* Samuels, Jr., H. H.; Tsai, J. S.; Casanova, J.; Stanley, F. (New York Univ. Med. Ctr., N.Y.). *J. Clin. Invest.* 54(4):853-865, 1974.

The kinetics of *in vitro* binding of ^{125}I-triiodothyronine and ^{125}I-thyroxine with GH_1 cells (a rat pituitary tumor cell line) and rat liver nuclear extract was examined at 0 C and 37 C. Equilibrium was attained within 5 min at 37 C and 2 hr at 0 C. The binding activity from GH_1 cells was stable for at least 1 hr at 37 C and 10 days at -20 C. Chromatography on a weak carboxylic acid column and inactivation by trypsin and pronase, but not by DNase or RNase, suggested that the putative receptor was a nonhistone protein. The estimated equilibrium dissociation constants for hormone binding to the solubilized nuclear binding activity were 1.80 X 10^{-10} M (triiodothyronine) and 1.20 X 10^{-9} (thyroxine) for GH_1 cells and 1.57 X 10^{-10} M (triiodothyronine) and 2.0 X 10^{-9} M (thyroxine) for rat liver. These values for triiodothyronine are virtually identical to those previously reported with isolated rat liver nuclei and GH_1 cell nuclei *in vitro*. The 10-fold greater affinity for triiodothyronine compared with thyroxine in the nuclear extract is also identical to that observed with intact GH_1 cells. In addition, the ^{125}I-triiodothyronine and ^{125}I-thyroxine high-affinity binding in the nuclear extract were inhibited by nonradioactive triiodothyronine or thyroxine, which suggests that the binding activity in the nuclear extract was identical.

8329 TIME-COURSE OF THE EFFECTS OF THYROID HORMONE ON RESPIRATION AND Na^+ + K^+-ATPase ACTIVITY IN RAT LIVER. *(E.)* Ismail-Beigi, F.; Edelman, I. S. (Univ. California Sch. Med., San Francisco). *Proc. Soc. Exp. Biol. Med.* 146(4):983-988, 1974.

As a test of the hypothesis that increased energy expenditure in active Na^+ transport mediates a major part of thyroid thermogenesis, time-course measurements were made of hepatic oxygen consumption (Q_{O2}), Na^+-dependent oxygen consumption [Q_{O2}(t)], and Na^+ + K^+ adenosine-triphosphatase (NaK-ATPase) activity after a single or repeated injections of triiodothyronine (50 μg/100 g) into thyroidectomized and euthyroid male Sprague-Dawley rats. In both groups, after single injections, Q_{O2} and Q_{O2}(t) increased to peak values at 48 hr and declined in parallel to close to the control level by the 6th day. In euthyroid rats, NaK-ATPase activity manifested the same time-course with a peak increase at 48 hr. In both groups, after repeated injections (every other day X 3), there were curvilinear increases in Q_{O2}, Q_{O2}(t) and NaK-ATPase activity to steady-state levels in 2-3 days. These findings are in accord with the inference that thyroidal stimulation of the Na^+ pump mediates the increase in Q_{O2}(t). In addition, it was found that there was an increase in Na^+-independent respiration and Mg-ATPase activity with a peak response at 48 hr in hypothyroid rats; this effect was transient even with repeated injections of triiodothyronine.

8330 ETHANOL OXIDATION BY COMPONENTS OF RAT LIVER MICROSOMES. *(E.)* Barakat, H. A.; Tapscott, E.; Pennington, S. (East Carolina Univ. Sch. Med., Greenville, N.C.). *Biochem. Biophys. Res. Commun.* 60(1):482-488, 1974.

Cytochrome P-450 was obtained from rat liver microsomes by a new purification method to determine whether the cytochrome alone and in combination with other fractions is involved in the oxidation of ethanol. Microsomal pellets from male albino Sprague-Dawley rats were solubilized in a solution consisting of 110 mM sucrose, 20 mM potassium chloride, 20 mM sodium citrate at pH 7.5, 1.25 mM DTT, 20% glycerol, and 0.5% deoxycholate. After stirring of the pellet in the solubilization buffer and centrifuging, the resultant supernatant solution was applied to a DEAE-cellulose column which was then washed with potassium phosphate buffer until the A_{280} of the eluate dropped to approximately 0.150. Cytochrome P-450 was then eluted with a linear 0.1 M-0.3 M potassium phosphate gradient. Fractions with a high P-450 specific activity were pooled and concentrated through a PM-10 Amicon filtration membrane, with the concentrate being applied to a Sephadex G-200 column and eluted with 0.4 M potassium phosphate buffer. Although 15% of the original P-450 was recovered through the purification process, only 0.8% of the total original microsomal ethanol oxidation activity was associated with this fraction. Addition of this purified fraction to other fractions isolated did not further stimulate ethanol oxidation. The component of rat liver microsomes that was most efficient in the oxidation of ethanol was the mixture of catalase and NADPH-cytochrome-c-reductase. The highly purified cytochrome P-450 did not by itself oxidize ethanol to any appreciable degree.

8331 NADPH-DEPENDENT OXIDATION OF METHANOL, ETHANOL, PROPANOL AND BUTANOL BY HEPATIC MICROSOMES. *(E.)* Teschke, R.; Hasumura, Y.; Lieber, C. S. (Bronx VA Hosp., New York, N.Y.). *Biochem. Biophys. Res. Commun.* 60(2):851-857, 1974.

The oxidation of methanol, ethanol, propanol, and butanol to their respective aldehydes was studied in a rat liver microsomal preparation in the presence of an NADPH regenerating system. All 4 alcohols were metabolized under these conditions; however, no aldehydes were produced from propanol and butanol in the presence of a peroxide (H_2O_2) generating system, whereas methanol and ethanol were oxidized also under these conditions. Controlled studies of the effect of chronic ethanol consumption on the microsomal alcohol oxidizing system of rat liver showed a 50-100% stimulation of specific activity depending on which of the 4 alcohol substrates was used. Pyrazole (0.1 mM), an alcohol dehydrogenase inhibitor, had no effect on microsomal alcohol oxidizing system activity, whereas alcohol oxidation was significantly inhibited by CO. These results indicate that the microsomal oxidizing system operates separately from catalase and from alcohol dehydrogenase and that it is responsible, at least partially, for the alcohol metabolism by the alcohol dehydrogenase-independent pathway of the liver.

8332 2,4-DINITROPHENOL-INDUCED INCREASE IN ETHANOL AND ACETALDEHYDE OXIDATION IN THE PERFUSED RAT LIVER. *(E.)* Eriksson, C. J. P.; Lindros, K. O.; Forsander, O. A. (Res. Lab. State Alcohol Monopoly, Helsinki, Finland). *Biochem. Pharmacol.* 23(15):2193-2195, 1974.

The mechanism of the 2,4-dinitrophenol (DNP)-induced stimulation of ethanol metabolism was examined using a once-through liver perfusion system so that the oxidation of both ethanol and the acetaldehyde derived from it, the cytosolic redox state, and oxygen consumption could all be determined in the same liver. Livers were used from male albino Wistar rats. In preliminary studies, 0.01, 0.02, and 0.05 mM DNP were passed consecutively through the same liver. Essentially the same effects were observed with each DNP concentration. There was a marked increase in both the ethanol and the acetaldehyde oxidation rate in the presence of DNP. Ethanol increased both oxygen consumption and the lactate/pyruvate ratio in the perfusion medium; DNP further stimulated oxygen uptake but lowered the lactate-pyruvate ratio. Although the increase in acetaldehyde and ethanol oxidation rates appears similar, the decreased acetaldehyde output during DNP infusion shows that the oxidation of acetaldehyde increased more than that of ethanol. This somewhat stronger stimulation of acetaldehyde oxidation supports at least partial intramitochondrial acetaldehyde oxidation.

8333 IN VITRO INHIBITION OF PROTEIN SYNTHESIS IN RAT LIVER AS A CONSEQUENCE OF ETHANOL METABOLISM. *(E.)* Perin, A.; Scalabrino, G.; Sessa, A.; Arnaboldi, A. (Inst. Gen. Pathol., Univ. Milan, Italy). *Biochim. Biophys. Acta* 366(1):101-108, 1974.

Hepatocyte protein synthesis was studied *in vitro* by measuring the rate of incorporation of isotopically labeled amino acids into acid-insoluble material of rat liver slices during incubation in ethanol (0.5 - 150 mM). Ethanol showed a dose-dependent inhibitory effect on protein synthesis which was most evident when radioactive leucine was used as a marker, reaching a maximum of 46% at 150 mM in fed rats compared to the uptake in controls. Removal of ethanol reversed the inhibition which was nearly twice as great in fed as in fasting rats. Pyrazole (2 mM), an alcohol dehydrogenase inhibitor, also prevented the protein inhibitory effect of ethanol. Concentrations of ethanol which were inhibitory in rat liver failed to inhibit protein synthesis in liver slices from guinea pigs which lack alcohol dehydrogenase. Acetaldehyde, the primary metabolite of ethanol, however, did inhibit guinea pig liver protein synthesis suggesting that ethanol metabolism is a necessary prerequisite. Acetaldehyde (10^{-4}M), but not acetoin (up to 5 mM), also inhibited rat liver protein synthesis. Sorbitol, which like ethanol decreases the NAD/NADH ratio in hepatocytes, inhibited rat liver protein synthesis while pyruvate (10 mM), which raises the NAD/NADH ratio was able to reverse the ethanol effect. These data show that the inhibition of rat liver protein synthesis by ethanol is a consequence of ethanol metabolism to acetaldehyde and is due also to a shifting of the redox potential of the cell.

8334 CHANGES IN MICROSOMAL AND MITOCHONDRIAL OXIDATION IN RAT LIVER DURING CONTINUOUS ADMINISTRATION OF PHENOBARBITOL. *(Rus.)* Chistiakov, V. V; Chernobrovkina, T. V.; Ratnikova, L. A.; Pospelova, L. I. (N. I. Pirogov 2nd Moscow Med. Inst., USSR). *Biokhimiia* 39(5):984-990, 1974.

White male rats were injected i.p. with phenobarbital (80 mg/kg/day for 20 days) to study the changes in the oxidative systems of microsomes and mitochondria. Cytochrome P-450 content and enzyme activity in the NADPH oxidation pathways in microsomes increased by 3.6 and 2.5 times normal, resp., 4 days after administration of the drug. Continued injection showed a decrease approaching the control level. Similar but less pronounced changes were observed in the microsomal NADH oxidation pathways. Increased activity in mitochondrial NADH oxidation was noted 2-3 days after the injection began, followed by a slight decrease in the next few days. The cytochrome b_5 content in mitochondria increased sharply in 6 days by the time tolerance to the drug hypnotic effect set in, and remained 2.5 times above normal in the subsequent period of phenobarbital administration. Comparison of the changes in the oxidative enzymes of hepatic microsomes and mitochondria suggests the involvement of the mitochondrial cytochrome b_5 in the "stand-by" oxidative system responsible for the phenobarbital detoxication in the continuous administration of the drug.

8335 HEPATIC AND SERUM LIPID PATTERNS DURING DEVELOPMENT OF PHENOBARBITAL INDUCED FATTY LIVERS IN RATS. *(E.)* Tuma, D. J.; Sorrell, M. F.; Barak, A. J. (VA Hosp., Omaha, Nebr.). *Proc. Soc. Exp. Biol. Med.* 146(4):953-956, 1974.

Lipids were measured in the livers and sera of male Sprague-Dawley rats weighing 250 g that had received phenobarbital injections (50 mg/kg sodium phenobarbital i.p. every 12 hr) for 3 days and 5 days. The same lipid patterns, including free cholesterol, cholesterol esters, phospholipids, triglyceride, and fatty acids, were determined in the livers and sera of rats 3 days and 5 days following withdrawal of the drug. Liver lipids increased with time while the drug was being administered and returned to normal when the drug was withdrawn. During phenobarbital administration as well as during withdrawal, the serum lipid levels did not change. These results suggest that decreased lipid transport and increased peripheral mobilization of fat do not play a major role in the pathogenesis of phenobarbital induced fatty liver.

8336 ACETAMINOPHEN-INDUCED HEPATIC INJURY: PROTECTIVE ROLE OF GLUTATHIONE IN MAN AND RATIONALE FOR THERAPY. *(E.)* Mitchell, J. R.; Thorgeirsson, S. S.; Potter, W. Z.; Jollow, D. J.; Keiser, H. (Natl. Heart Lung Inst., Bethesda, Md.). *Clin. Pharmacol. Ther.* 16(4):676-684, 1974.

The metabolism of acetaminophen (900, 1200, or 1800 mg administered p.o. at 48 hr intervals) was studied in 12 healthy male and female human volunteers. Chromatographic analysis of urinary metabolites in 2 subjects who had ingested ^{3}H-acetaminophen (1200 mg) indicated that 84% of the administered dose was excreted in 12 hr. Of the total urinary radioactivity, 2.1% was associated with free acetaminophen, 52.1% and 42.0% with the parahydroxy sulfate and glucuronide conjugates, resp., and 3.8% with the mercapturic acid conjugate. In 10 other subjects who ingested unlabeled acetaminophen, the formation of acetaminophen-mercapturic acid was proportional to the dose of the drug. In parallel animal studies, pretreatment with cysteamine (150 mg/kg) and dimercaprol (80 mg/kg), protected mice from acetaminophen-induced hepatic necrosis. Treatment with cysteamine within 1 hr after acetaminophen ingestion reduced the mortality rate and severity of hepatic necrosis. Cysteamine, however, had no protective effect if given 2 or 3 hr after acetaminophen. Pretreatment with cysteamine failed to alter the rate of acetaminophen absorption or metabolism in mice. *In vitro* studies showed that cysteamine decreased the cytochrome P-450-dependent arylation by acetaminophen of hepatic microsomal proteins but had no effect on the metabolism of ethylmorphine, another substrate of the cytochrome P-450 system; this finding suggested that cysteamine acted by combining directly with the electrophilic metabolite of acetaminophen. These results suggest that patients overdosed with acetaminophen may logically be treated with cysteamine or similar compounds.

8337 REGULATION OF GLUCOSAMINE SYNTHESIS DURING THE FIRST TWENTY-FOUR HOURS FOLLOWING INJURY AND PARTIAL HEPATECTOMY. *(E.)* Okubo, H.; Chandler, A. M. (Univ. Oklahoma Sch. Med., Oklahoma City). *Proc. Soc. Exp. Biol. Med.* 146(4):1159-1162, 1974.

The activity of glucosamine synthetase and the concentration of uridine diphospho-*N*-acetylhexosamine (UDPAH) were measured concomitantly during the first 24 hr following laparotomy or partial hepatectomy in male albino rats weighing 150-250 g. Glucosamine synthetase activity increased significantly above normal by 12 hr following laparotomy, rose rapidly to peak values of 60-100% above normal by 18 hr, and then declined at variable rates. UDPAH concentrations rose and fell in parallel with the fluctuations in enzyme activity. Glucosamine synthetase activity showed little or no response after partial hepatectomy until about 20-24 hr when variable rates of increase occurred. The UDPAH concentrations remained constant until 14-18 hr after which a significant decrease occurred.

8338 EFFECT OF DRUG PRETREATMENT ON $CBrCl_3$-INDUCED IVER INJURY. *(E.)* Torielli, M. V.; Ugazio, G.; Gabriel, L.; Burdino, E. (Inst. Gen. Pathol., Univ. Turin, Italy). *Toxicology* 2(4):321-326, 1974.

The effects on $CBrCl_3$-induced liver toxicity of 2-diethylaminoethyl-2,2-diphenylvalerate (SKF-525A), an inhibitor of microsomal mixed-function oxidases, and of *N,N'*-diphenyl-*p*-phenylenediamine (DPPD), a mixed-function oxidase inhibitor with antioxidant properties, were studied in fasting male Wistar rats pretreated with phenobarbital. The marked double-bond shifting in purified liver microsomal lipids as determined by a shift in the UV absorption spectrum and observed 60 min after intragastric administration of 10 µl $CBrCl_3$/100 g was enhanced 50% by phenobarbital pretreatment (total of 18 mg/100 g i.p.). Pretreatment with SKF-525A (5 mg/100 g i.p.) or DPPD (60 mg/100 g i.p.), however, lowered the $CBrCl_3$-induced peroxidative decomposition of unsaturated lipids. Fatty liver, as determined by the rate of hepatic triglyceride accumulation, was significantly enhanced in phenobarbital-pretreated rats but was almost completely prevented by SKF-525A and DPPD. Prior treatment with small doses of CCl_4(25 µl/100 g p.o.) partially protected animals against the lethal effect of $CBrCl_3$. These results suggest that the lethal effect of $CBrCl_3$ depends on the efficiency of the hepatic microsomal drug-metabolizing enzyme systems.

8339 EFFECT OF LIGATION OF THE HEPATIC ARTERY OR OCCLUSION OF THE PORTAL VEIN ON THE DEVELOPMENT OF ENDOTOXEMIA. *(E.)* Gans, H. (no affil.). *Surg. Gynecol. Obstet.* 139(5):689-692, 1974.

Twenty-three male Sprague-Dawley rats were given tetracycline (2.5 mg) 10-15 min after undergoing hepatic artery ligation. Every rat survived and continued to thrive. A similar group of 23 rats receiving lead acetate (3 1/2 mg/100 g i.v.) 15-20 min after ligation also survived. Thirteen of 15 rats subjected to the same procedure but without the tetracycline protection died after lead acetate administration. Portal vein occlusion for 30 min was well tolerated in 6 rats receiving single doses of 0.05 ml heparin preoperatively and 2.5 mg tetracycline i.m. postoperatively. Upon release of the portal vein occlusion, the congested intestine slowly resumed normal color over the course of 2-10 min, while the liver quickly resumed its normal color. All rats survived lead acetate injection. When this study was repeated without heparin or tetracycline protection, all 10 rats submitted to tourniquet occlusion of the portal vein for 30 min tolerated administration of lead acetate. There was no evidence to suggest the development of systemic endotoxemia after hepatic artery ligation or after 30 min of portal venous occlusion. The findings suggest that in the rat during a 30-min interruption of portal vein blood flow, the hepatic artery flow is quite sufficient to maintain life and sustain subsequent growth.

8340 FATTY LIVERS INDUCTION BY OROTIC ACID CONTAINED IN SKIM MILK POWDER. *(E.)* Okonkwo, P. O.; Kinsella, J. E. (Fac. Med., Univ. Nigeria, Enugu). *Experientia* 30(9):993-994, 1974.

Thirty female Sprague-Dawley rats, weighing 155 to 165 g, were divided into 3 groups of 10 each and fed a control diet, the control diet plus 0.15% orotic acid, and a skim milk powder diet containing 0.15% orotic acid, resp. The 3 diets were isocaloric and contained the identical casein protein content. Five rats were sacrificed from each group after 3 and 8 days, the livers removed, the amount of lipid determined, and the lipid content analyzed for component fatty acids by gas-liquid chromatography. There was a marked increase in total lipid content of the liver which increased progressively with orotic acid feeding. Steatosis was visible in orotic acid-treated rats. The low concentration of orotic acid used, combined with the use of mature rats might account for the lack of drug-induced hepatic hypertrophy observed in previous studies. The presence of calcium and lactose in the powdered milk did not protect against fatty liver.

8341 BILIARY EXCRETION AND ENTEROHEPATIC CIRCULATION OF [^{14}C]HYDROXYTRYPTAMINE IN NORMAL AND CIRRHOTIC RATS. *(E.)* Kekki, M.; Pentikainen, P.; Mustala, O. (Dept. Pharmacol., Univ. Helsinki, Finland). *Gastroenterology* 67(4):700-708, 1974.

^{14}C-Serotonin (11 μg/kg) was administered intraportally to normal and cirrhotic male Sprague-Dawley rats, and urine and bile were collected periodically for periods up to 6, and occasionally up to 10 hr. ^{14}C-Serotonin metabolites were separated using 2-dimensional paper chromatography, and the radioactivity of 9 metabolites of serotonin was measured by liquid scintillation spectroscopy. Cirrhotic rats excreted ^{14}C metabolites into urine in less quantity than did normal rats. In addition, the biliary excretion of labeled metabolites was markedly depressed in cirrhotic rats. The preferential occurrence of glucuronide conjugates was demonstrated in both the urine and bile of cirrhotic animals. ^{14}C-5-Hydroxytryptophol conjugates decreased and ^{14}C-serotonin conjugates increased in cirrhotic rats. In normal animals, at least 1/3 of the ^{14}C-serotonin metabolites excreted into the bile go through the enterohepatic circulation, and a significant proportion of these can be found again in bile after intrajejunal administration of prelabeled bile.

8342 DRUG METABOLISM IN EXPERIMENTAL CHOLESTASIS. *(Ger.)* Richter, E.; Grun, M.; Zilly, W.; Brachtel, D.; Kuhn, H. A. (Med. Clin., Univ. Wurzburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1402-1404, 1972.

Cholestasis was induced in albino rats (FW 49 strain) by administration of 100 mg/kg of α-naphthylisothiocyanate (ANIT) p.o. In the livers of these rats, NADPH-cytochrome *c* reductase activities and cytochrome P-450 contents were almost normal, but the duration of hexobarbital sleep was increased and the maximum hexobarbital tolerance was decreased. If rats were pretreated with phenobarbital (50-80 mg/kg i.p. in increasing doses on 4 successive days) before administration of ANIT, drug-metabolizing enzymes in the liver were activated with increases in the cytochrome P-450 content and NADPH-cytochrome *c* reductase activities. The duration of hexobarbital sleep was reduced and maximum hexobarbital tolerance was increased. However, phenobarbital pretreatment increased the severity of ANIT-induced cholestasis, as determined by clinical, chemical, and morphological investigations. ANIT-induced cholestasis produced functional impairment of drug metabolism which was eliminated by phenobarbital pretreatment. On the basis of these results, the drug-metabolizing enzymes do not appear to be involved in the development of cholestasis.

8343 SURGICAL RESEARCH ASPECTS OF HEPATIC REGENERATION. *(E.)* Hays, D. M. (Univ. Southern California Sch. Med., Los Angeles). *Surg. Gynecol. Obstet.* 139(4):609-619, 1974.

SECRETION AND METABOLISM

Intestine

8396 ENTEROCHROMAFFIN CELLS OF THE MAMMALIAN SMALL INTESTINE AS THE SOURCE OF MOTILIN. *(E.)* Pearse, A. G. E.; Polak, J. M.; Bloom, S. R.; Adams, C.; Dryburgh, J. R.; Brown, J. C. (Hammersmith Hosp., London, England). *Virchows Arch.* [*Zellpathol.*] 16(2):111-120, 1974.

The 22-amino acid peptide motilin was found in the enterochromaffin cells (EC) of the duodenum and jejunum by immunofluorescence and electron microscopy. Samples of mucosa were taken from the stomach, mid and lower duodenum, upper and lower jejunum, upper and lower ileum, and upper and lower colon of 2 dogs, 2 young pigs, and 1 baboon, and a further series of samples from 5 human subjects at operation. Fluorescent motilin cells were detected in the mucosa of all species tested. In the duodenum and jejunum, no argentaffin cell was found which did not contain motilin. In the stomach and colon, on the other hand, no motilin immunofluorescence was found in the EC cells or elsewhere. Early speculation that the protein present in the 5-hydroxytryptamine-storing granules of the EC cell would be found to be a polypeptide hormone are thus confirmed.

8397 THYROXINE-EVOKED PRECOCIOUS DECREASE OF ACID HYDROLASES IN THE ILEUM OF SUCKLING RATS. *(E.)* Koldovsky, O.; Jumawan, J.; Palmieri, M. (Children's Hosp., Philadelphia, Pa.). *Proc. Soc. Exp. Biol. Med.* 146(3):661-664, 1974.

The involvement of the thyroid in the maturation of the small intestine was studied in Charles River rats. Thyroxine (200 μg/100 g, s.c.) was administered every 24 hr to intact suckling rats (from day 7 to 13 of age) and to suckling adrenalectomized rats (from day 14 to 18 of age). Thyroxine-treated intact animals gained less weight than control rats, their fur appeared more mature, and their eyes opened sooner. Thyroxine did not influence the body weight of adrenalectomized rats, but it did cause a decrease in the weight of the ileum expressed both as total mg of protein and as total mg wet weight. Thyroxine evoked a substantial decrease of activity of acid-β-galactosidase, N-acetyl-β-glucosaminidase and β-glucuronidase in the ileum of suckling rats from both groups. Thus, the decrease in acid hydrolase activity was not secondary to stimulation of the adrenals. Thyroxine also evoked a precocious increase of jejunal sucrase and maltase activities in suckling rats. These results support the maturative role of the thyroid in the development of the small intestine.

8398 ACTION OF Escherichia coli ENTEROTOXIN: ADENYLATE CYCLASE BEHAVIOR OF INTESTINAL EPITHELIAL CELLS IN CULTURE. *(E.)* Kantor, H. S.;

Tao, P.; Wisdom, C. (Hektoen Inst. Med. Res., Chicago, Ill.). *Infect. Immun.* 9(6):1003-1010, 1974.

Enterotoxin response of human embryonic epithelial cells in culture was compared to that in the adult rabbit ileal loop model. Heat-labile enterotoxin preparations obtained from 2 enteropathogenic strains of *Escherichia coli* of porcine and human origin were shown to stimulate adenylate cyclase activity of human embryonic intestinal epithelial cells in culture. Comparable results were also obtained when *Vibrio cholera* enterotoxin was used. In general, degree of enzyme stimulation was proportional to the concentration of enterotoxin. Similar preparations from 2 strains of non-enterotoxigenic *E. coli* had no effect on adenylate cyclase activity. During long periods (18 hr) of tissue culture incubation, the determination of adenylate cyclase activity was 200-300 times more sensitive than quantitating fluid accumulation in the adult rabbit ileal loop models. Decreasing the incubation time appreciably reduced the sensitivity of the epithelial cells to enterotoxin. It was also found that *E. coli* enterotoxin was an effective activator of nonintestinal adenylate cyclase systems. Treatment of 2 other cell lines, a human epitheloid carcinoma and a human carcinoma of the larynx, with enterotoxin also resulted in significant enzyme stimulation. Results obtained here indicate that the intestinal epithelial cell tissue culture model provides a sensitive homogenous biological system for studying the response of intestinal adenylate cyclase to enterotoxin while eliminating the numerous cellular and tissue components present in the ligated ileal loop model.

8399 CELLS INVOLVED IN THE IMMUNE RESPONSE. XXVII. THE DEMONSTRATION OF APPENDIX-SPECIFIC ANTIGENS IN THE RABBIT. *(E.)* Colas de la Noue, H.; Richter, M. (Roy. Victoria Hosp., Montreal, Canada). *Immunology* 27(3):421-426, 1974.

The existence of appendix lymphocyte-specific antigens in the rabbit was investigated. Rabbit appendix cells were injected i.v. into horses at weekly intervals after which the horses were bled and the sera tested for cytotoxic activity. The unabsorbed antiserum was cytotoxic to the lymphocytes of all the lymphoid organs tested. Following absorption with bone marrow and thymus cells, the antiserum lost all cytotoxic activity directed toward these cells but displayed almost undiminished cytotoxic activity toward the cells of the saculus rotundus, appendix and Peyer's patches. The absorbed antiserum also demonstrated cytotoxic activity toward certain lymphocytes present in the spleen, lymph node and circulation. Thus, the antibodies directed toward the antigens common to all lymphoid cells were removed by the thymus and bone marrow cells, leaving behind cytotoxic antibodies directed toward antigens present on appendix and appendix-derived cells only. The results suggest that less than 50% of the spleen and circulating cells and about 60% of the lymph node lymphocytes are appendix-derived cells or cells which carry the appendix lymphocyte-specific antigen markers.

GENERAL

8420 EFFECT OF PORTAL VENOUS PRESSURE ON PORTAL VENOUS INFLOW AND SPLANCHNIC RESISTANCE. *(E.)* Mitzner, W. (Dept. Biomed. Eng., Johns Hopkins Univ., Baltimore, Md.). *J. Appl. Physiol.* 37(5):706-715, 1974.

The effect of portal venous pressure on the prehepatic splanchnic vascular resistance was studied in 2 unanesthetized and 12 anesthetized dogs (25 mg/kg pentobarbital). A hydraulically actuated cuff occluder was placed on the portal vein between the gastroduodenal vein and the liver, and an electromagnetic flow probe was placed around the portal vein between the gastroduodenal and gastrosplenic veins to measure portal venous flow. The experimental procedure consisted of inflating the occluder by graded amounts to produce varying degrees of upstream portal pressure elevation. Occlusions were held until the portal pressure and portal flow reached steady values (usually about 1 min). In 2 additional animals the placing of catheters, probe, and occluder was done under sterile conditions. The splanchnic resistance increased linearly with increases in portal pressure for all of the animals studied. The mean control arterial pressure was 119 ± 4 mm Hg, and the mean control portal venous pressure was 9.7 ± 0.7 mm Hg. The mean control value of splanchnic resistance was 7.9 ± 0.6 mm Hg/(ml/min/kg). The response was apparently not mediated *via* a synaptic neural mechanism since administration of 0.5 mg/kg of the ganglionic blocker pentolinium tartrate to 2 animals did not alter the response of splanchnic resistance to increases in portal pressure. Rapid splenectomy on 2 animals increased the pressure dependence of the remaining splanchnic resistance. The portal-splanchnic response observed suggests that alterations in total hepatic blood flow may be more effectively accomplished by changes in portal venous rather than hepatic arterial resistance. This response may also be partly responsible for the greatly decreased portal venous flow found in patients with cirrhosis.

DIAGNOSTIC PROCEDURES

8429 DETECTION OF RECURRENCE OF LARGE-BOWEL CARCINOMA BY RADIOIMMUNOASSAY OF CIRCULATING CARCINOEMBRYONIC ANTIGEN (C.E.A.). *(E.)* Mach, J. P.; Jaeger, P.; Bertholet, M. M.; Ruegsegger, C. H.; Lossli, R. M.; Pettavel, J. (Inst. Biochem., Univ. Lausanne, Switzerland). *Lancet* (7880):535-540, 1974.

The usefulness and limitations of the carcinoembryonic antigen (CEA) radioimmunoassay for the evaluation of tumor resection and the detection of tumor relapse were studied in 101 patients with histologically proven adenocarcinoma of the colon or rectum. Plasma-CEA levels were determined before any treatment. A preoperative CEA value of 5 ng/ml or higher was found in 71% of all the patients and 63% of cases with localized tumor (Dukes A and B). This limit was reached by only 1 of 90 apparently healthy, nonsmoking blood-donor controls. A return to normal CEA levels occured in 40 of 45 patients following complete tumor resection. Subsequent elevations in CEA levels were observed in the 5 patients whose CEA did not fall below 5 ng/ml following surgery. All 5 exhibited subsequent tumor relapse. Follow-up studies of 22 of the surgical patients with repeated CEA radioimmunoassay for several months after surgery revealed progressively increasing CEA levels preceding clinical diagnosis of tumor relapse by 2-10 months for 8 patients. Six other patients showed a moderate increase in CEA levels, suggesting a tumor relapse not yet clinically detectable. The remaining 8 patients showed no increase in CEA level above 5 ng/ml and had no clinical symptoms of relapse. It is concluded that an incomplete drop of circulating CEA level 1 month after surgery appears to have a bad prognostic significance.

8430 HETEROGENEITY OF CARCINOEMBRYONIC ANTIGEN AND ITS FRACTIONATION BY CON A AFFINITY CHROMATOGRAPHY. *(E.)* Rogers, G. T.; Searle, F.; Bagshawe, K. D. (Charing Cross Hosp., London, England). *Nature (Lond.)* 251(5475):519-521, 1974.

Carcinoembryonic antigen (CEA) prepared from a large liver metastasis was separated with con A-Sepharose chromatography into 3 immunologically active fractions to demonstrate the heterogeneous nature of the antigen's composition. Antisera were prepared in rabbits by injecting into the flank 200 μg of a purified batch of CEA (M-12) in Freund's adjuvant. After extensive absorption with pooled normal colonic mucosa extract, normal human plasma, and liver extract, antiserum 174 produced an identical double diffusion reaction with all 3 fractions as well as an additional reaction with only 1 of the fractions. Various other antisera, such as "ace" 10, 22, 24, and 36 reacted similarly to antiserum 174, giving a single line of identity between all 3 fractions. Similar results were obtained with a later CEA preparation (M-31). The results indicated that CEA can be separated into at least 2 immunologically related fractions that contain determinants which can be distinguished by appropriate antisera. These fractions, however, remain indistinguishable by anti-CEA antisera such as Todd "ace" antisera which appear to react with a group common to each of the fractions. Further fractionation of CEA preparations may afford reagents for improving the specificity of the CEA assay and indicate whether circulating CEA shows a similar heterogeneity to preparations isolated from tumor tissue.

8431 SELECTIVE ARTERIOGRAPHY COMBINED WITH HYPOTONIC DUODENOGRAPHY FOR PANCREATIC LESIONS. *(E.)* Suzuki, T.; Uchida, K.; Tani, T.; Honjo, I. (Kyoto Univ. Med. Sch., Japan). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):398-405, 1974.

Five case reports of suspected pancreatic lesion are presented to illustrate the diagnostic value of selective arteriography combined with hypotonic duodenography. Selective arteriography showed irregular stenosis of both anterior superior and posterior superior pancreaticoduodenal arteries in a 41-yr-old female, but neither proliferated tumor vessels nor tumor stain were demonstrable. A duodenogram showed the circumferential constriction with an incisura defect of the mid-descending duodenum, suggestive of direct invasion by the pancreatic lesion toward the duodenum. The combination of vascular and duodenal images showed the extent of a carcinoma originating on the posterior surface of the head of the pancreas in a 45-yr-old female; the growth of the tumor could not be assessed by angiography alone. Use of the combined diagnostic procedure in a 58-yr-old male suggested that a duodenal deformity was due to compression by an enlarged gallbladder rather than to invasion by a carcinoma of the head of the pancreas. Combined duodenography-arteriography in a 65-yr old male resulted in a final diagnosis of carcinoma of the ampulla of Vater; simple arteriography indicated no pathology except for very meager findings in the finer branches of the pancreaticoduodenal arcades and distention of the cystic artery. Hypotonic duodenography combined with common hepatic arteriography suggested that a 69-yr-old male with cholangiolitic hepatitis was free of a pancreaticoduodenal lesion. All of the above diagnostic findings were confirmed by laparotomy. The combined roentgenogram is more useful than the summation of findings noted on 2 roentgenograms taken separately and permits identification of the precise location of vessels supplying the pancreas, visualization of the extent of the pancreatic lesion, confirmation of minimal changes in the finer vessels, and appropriate therapeutic planning.

8432 THE VALUE OF ULTRASONIC SCANNING IN THE DIAGNOSIS OF INTRA-ABDOMINAL ABSCESSES AND HEMATOMAS. *(E.)* Jensen, F.; Pedersen, J. F. (Gentofte Hosp., Copenhagen, Denmark). *Surg. Gynecol. Obstet.* 139(3):326-328, 1974.

Ultrasonic scanning examinations of intra-abdominal abscesses or hematomas were analyzed for 50 patients whose final diagnoses were obtained at surgery, by aspiration, spontaneous perforation, or at autopsy. Echo-informations during ultrasonic scanning were collected from a selected plane and placed at correct mutual relationships on a memory oscilloscope to form a sectional picture. Intra-abdominal hematomas and abscesses appeared as almost echo-free areas which disturbed the shape, localization, or inner structure of echo-giving organs. Suspected hematoma or abscess was confirmed in 31 of 34 patients, and negative diagnosis was correct in 12 of 16 patients. A large subphrenic abscess was revealed during surgery in one of 4 false-negative patients, while the remaining 3 were diagnosed as having abscesses from pus production. A carcinoma of the cecum was misdiagnosed as a multi-loculated abscess in one of 3 false-positive diagnoses. A local recurrence of a hypernephroma was ultrasonically diagnosed as an abscess or a hematoma in another patient. The ultrasonic findings in 2 examinations were inconclusive. Ultrasonics is unable to differentiate between an abscess and a hematoma; this distinction must be based on clinical data. Both lesions, however, are not as sharply circumscribed as cysts.

8433 DEMONSTRATION OF THE ABNORMAL LIPOPROTEIN OF CHOLESTASIS, LP-X, BY PRECIPITATION WITH POLYANION.

(E.) Ritland, S. (Rikshosp., Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol* 9(5): 507-510, 1974.

Duplicate unfrozen serum or plasma samples from 96 patients with manifest or suspected liver disease and 4 patients with familial lecithin-cholesterol acyltransferase (LCAT) deficiency were examined for the abnormal lipoprotein X(LP-X) with immunoprecipitation and with polyanion-precipitation. The LP-X was electrophoretically separated from other lipoproteins and was tested by precipitation with anti-LP-X and by precipitation with polyanion. Immunoprecipitation detected LP-X in 40 samples, and this was confirmed by polyanion-precipitation in 39. Both methods were positive for 1:6 serial dilution and negative for 1:8 serial dilution. Concentrations of LP-X as low as 3.3 mg/100 ml were detectable by both methods. The LP-X test performed with polyanion-precipitation appears to be as reliable as the immunoprecipitation test and deserves wider use in the routine analysis of patients with liver disorders.

8434 LONG-TERM BODY RETENTION OF RADIOCOPPER (^{67}CU) AND THE DIAGNOSIS OF WILSON'S DISEASE.

(E.) Willvonseder, R.; Goldstein, N. P.; Tauxe, W. N. (Mayo Grad. Sch. Med., Univ. Minnesota, Rochester). *Mayo Clin. Proc.* 49(6):387-393, 1974.

Long-term body retention studies with ^{67}Cu were performed on 73 subjects to establish criteria for abnormal copper kinetics with this isotope and to investigate the isotope's value in the diagnosis of Wilson's disease. The following groups of patients were studied: 10 normal controls, 11 parents of patients with Wilson's disease (obligatory heterozygotes), 23 patients with a definite diagnosis of Wilson's disease (temporarily off penicillamine therapy), 17 relatives (other than parents or offspring) of patients with definite Wilson's disease, 10 patients with neurologic disorders, and 2 patients with liver disease (portal cirrhosis and fatty liver). In addition, 12 of the homozygous Wilson's disease patients were evaluated while on penicillamine treatment. Injections of 100 μC of carrier-free ^{67}Cu were administered i.v., and body retention at the end of each 24-hr period was calculated by subtracting the cumulative excreted activity (expressed as a percentage of the dose) from 100%. Plasma incorporation was computed by sampling blood at 10, 20, 30, 100, and 200 min after injection and then once daily on consecutive days. The mean value of retention half-times for homozygous Wilson's disease patients based on a 5-day observation period was about 150 days as compared to mean values of about 50 and 25 for patients heterozygous for Wilson's disease gene and normals, resp. Body retention of ^{67}Cu in homozygous Wilson's disease patients on D-penicillamine treatment was in the normal or carrier range, and 7 relatives of known Wilson's disease patients were normal. Most of the patients with neurological disorders were also in the normal or carrier range. One patient with portal cirrhosis was in the Wilson's disease range (120 day retention time). Discrimination of the various groups with ^{67}Cu studies was inferior to results obtained from previous studies using the shorter-lived ^{64}Cu isotope. A possible explanation might be an effect of the carrier copper on biliary excretion of copper and on individual bowel habits. Long-term body retention studies and simultaneous determination of plasma incorporation of ^{67}Cu with carrier copper might yield better discrimination of patients homozygous and heterozygous for Wilson's disease from the normal population.

8435 SENSITIVITY OF SERUM BILE ACID ASSAY FOR DETECTION OF LIVER DAMAGE IN VIRAL HEPATITIS TYPE B.

(E.) Hofmann, A. F.; Korman, M. G.; Krugman, S. (Mayo Clin., Mayo Fdn., Rochester, Minn.). *Am. J. Dig. Dis.* 19(10):908-910, 1974.

The sensitivity of serum bile acid radioimmunoassay for the detection of liver damage (viral hepatitis type B) was assessed by comparing the method with determinations of SGOT, bilirubin, and hepatitis B antigen in 5 children with mild, spontaneously remitting viral hepatitis (induced by parenteral inoculation with MS-2 serum). A serum cholyl conjugate value of 2 μM was used as the upper limit of normal for the bile acid assay. Increased bile acid values were observed in 15 of 47 serum samples, while 16 samples showed increased SGOT values. All patients were detected by both tests, and the time course of abnormal values was roughly similar for each test. Antigenemia preceded an elevation in transaminase or bile acid in 4 of 5 patients by 1-6 weeks. Serum bilirubin levels remained within normal limits in all patients but 1; in the latter bilirubin increased at the 10th week, when marked increases of serum bile acids and SGOT occurred. The serum bile acid values were as sensitive as SGOT values for detecting impaired liver functions in the patients with viral hepatitis and were a more sensitive index of liver damage than serum bilirubin in 4 patients who remained anicteric. Although the radioimmunoassay procedure used measures only cholyl conjugates, these may increase even more than dihydroxy bile acids in viral hepatitis.

8436 CONTRAST ROENTGENOGRAPHY IN THE MANAGEMENT OF MAJOR LIVER INJURY. *(E.)* Ayella, R. J.; Champion, H. R.; Gill, W.; Hankins, J. R.; Cowley, R. A. (Univ. Maryland Hosp., Baltimore). *Surg. Gynecol. Obstet.* 139(4):545-550, 1974.

The use of contrast roentgenography in the management of major liver injury is examined. During laparotomy for abdominal trauma, a Bakes dilator is gently passed into the portal vein, and a No. 8 to 10F soft plastic cannula is passed through the umbilical vein into the left portal vein and into the main portal vein. The umbilical vein is tethered to the skin by a suture to facilitate postoperative manipulation of the catheter. After an hepatic operation, a portable umbilical portohepatogram is performed. A survey film is made to identify the location of the catheter tip by its radiopaque marker line. A bedside portohepatogram is used essentially as a screening procedure in the early postoperative period or when the patient cannot be safely transported to specialized facilities. Obstruction of a portal vein branch or a filling defect in the sinusoidal phase is an indicator for further angiographic studies. The portohepatogram conducted in the angiographic suite may provide clues to indicate an expanding intrahepatic lesion. Veins appearing to be cut off or obstructed in a single portable view may in the more detailed examination be shown to exhibit some inequality in filling. The arteriogram will confirm the presence of a hematoma based on curvilinear arteries and a filling defect in the sinusoidal phase. The arteriogram and portohepatogram are of further value in determining the presence of perihepatic hematomas or abscesses as demonstrated by an increase in the space between the liver and surrounding structures. The hepatic venogram is predominantly used to demonstrate to the surgeon the proximity of large hepatic veins to the lesion.

8437 THE VALUE OF THE LATERAL ABDOMINAL ROENTGENOGRAM IN THE DIAGNOSIS OF NEONATAL HEPATIC PORTAL VENOUS GAS (HPVG). *(E.)* Kirks, D. R.; O'Byrne, S. A. (Brooke Army Med. Ctr., Fort Sam Houston, Tex.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(1):153-158, 1974.

The value of the lateral abdominal roentgenogram in the diagnosis of neonatal hepatic portal venous gas (HPVG) is illustrated with 3 case reports. A lateral abdominal roentgenogram confirmed the presence of pneumatosis intestinalis and HPVG in a 1786 g female (37 week gestation); a prior anteroposterior supine abdominal roentgenogram had demonstrated bowel distention, probable air within the bowel wall, and possible HPVG. The presence of HPVG was also confirmed by the lateral view in a premature 1068 g male (30 week gestation) displaying a rounded lucency just medial to the stomach on a anteroposterior abdominal roentgenogram. Evidence of HPVG in a 2052 g male (spontaneously delivered) was indicated only on the lateral view. The anteroposterior supine abdominal view in this case had revealed bowel distention and a mottled pattern in the left upper quadrant. The lateral abdominal roentgenogram may be obtained with either a vertical or horizontal beam. The roentgenologic appearance of HPVG on the lateral abdominal roentgenogram is manifested as a stellate lucency in the liver. The stellate appearance is believed to be due to contrast material seen end-on in large hepatic portal vein branches; surrounding and radiating linear densities are due to smaller peripheral branches.

8438 ANGIOGRAPHY OF THE JAUNDICED PATIENT WITH EMPHASIS UPON THE ANGIOGRAPHIC APPEARANCE OF BILIARY DUCT DILATION. *(E.)* Sprayregen, S.; Messinger, N. H. (Montefiore Hosp. Med. Ctr., Bronx, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):335-355, 1974.

Selective visceral angiograms of 61 jaundiced patients were reviewed, with emphasis on the angiographic appearance of dilated hepatic ducts with obstructive jaundice. The angiography in these patients usually consisted of sequential anteroposterior celiac and right posterior oblique superior mesenteric arteriograms. Obstruction of the common bile duct was seen in 40 patients who had not had cholecystectomies; gallbladder dilatation was seen in 36 of these. Gallbladder distension in patients without cholecystectomies was present in 26 of 29 cases with carcinoma of the head of the pancreas, 1 case of carconoma of papilla of Vater, 1 case of lymphosarcoma of the head of the pancreas, 2 cases of gallbladder carcinoma, 3 cases of carcinoma of the common bile duct, 4 cases of calculi of the common bile duct, and 1 case of compression of the common hepatic duct. Dilated hepatic ducts were often present with obstruction; when dilated, the right hepatic ducts were usually more clearly demonstrated than the left hepatic ducts. Ductal defects were best demonstrated in the capillary and venous phases of the celiac arteriogram. The hepatic ducts as visualized on the angiograms were dilated in 29 of 54 patients with obstructive jaundice. No evidence of dilated ducts was noted in any of 7 patients with nonobstructive jaundice. The arteriogram appears to be very useful in suggesting whether jaundice is of the obstructive or nonobstructive type and, if obstructive, in determining the site and extent of the obstructing lesion.

8439 DYNAMIC STUDIES ON THE PORTAL HEMODYNAMICS BY SCINTIPHOTOSPLENOPORTOGRAPHY: THE VISUALIZATION OF PORTAL VENOUS SYSTEM USING ^{99m}Tc. *(E.)* Kashiwagi, T.; Kamada, T.; Abe, H. (Osaka Univ. Med. Sch., Japan). *Gastroenterology* 67(4):668-673, 1974.

The technique of scintiphotosplenoportography, which permits visualization of portal venous system by injection of $^{99m}TcO_4-$ into the spleen and follows its course through the portal circulation, was used to study 33 patients with the following diagnoses: hemolytic anemia (2), cholelithiasis (1), pulmonary tuberculosis (1), chronic cholangitis (1), acute hepatitis (1), chronic hepatitis (11), cirrhosis (9). fibrosis (2), idiopathic portal hypertension (2), liver cell carcinoma (1), carcinoma of the pancreas (1), and carcinoma of the gall bladder (1). Three types of images were obtained with this technique: in type I, the normal course of portal circulation progressing through splenic vein, portal vein, and liver was observed; in type II, the presence of abnormal portosystemic collateral channels was detected, but the predominant flow was to the liver; and in type III, diversion of the injection through portosystemic collaterals took place and no liver image was obtained. This technique also allowed quantitation of circulation times from spleen to liver and from spleen to heart. Scintiphotosplenoportography provides a method for evaluating and quantitating flow in the portal circulation. Insofar as the resolution of scintiphotosplenoportography is concerned, it falls considerably short relative to roentgenography.

8440 POSITIVE IMAGING OF LIVER TUMORS BY DELAYED HEPATIC SCINTISCANNING WITH ACIDIC IONIC INDIUM 113m CHLORIDE. *(E.)* Cuaron, A.; Gordon, F.; Rodriguez, C. (Natl. Med. Ctr., Mexican Inst. Social Security, Mexico City). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):318-326, 1974.

The diagnostic potential of delayed hepatic scanning with indium^{113m} chloride for differentiating "cold" areas produced by liver tumors with poor vascularity from those caused by hepatic cysts and abscesses was explored in 13 patients with hepatic primary carcinomata and 9 with metastases to the liver. A radiocolloid liver scan was first obtained 10 min after i.v. administration of 2 mC of In^{113m}-iron. A few hr later, or on the next day, a 2nd liver scan was procured 10 min after i.v. administration of 10 mC of ionic, carrier-free acidic In^{113m} chloride to depict the spacial distribution of the hepatic blood pool. A 3rd scan was obtained 6 hr after In^{113m} administration. Six hr after the i.v. In^{113m} administration, the cardiac blood pool still retained 24 ± 2% of the radioactivity detected 10 min after the administration of the radiopharmaceutical in contrast to a 36 ± 6% retention at the normal hepatic region and a 54 ± 10% retention at the site where the concentration defect was found with the radiocolloid. Tumor/liver radioactivity ratios were 0.09 ± 0.05 for the radiocolloid, 0.51 ± 0.16 10 min after administration of In^{113m} chloride, and 0.76 ± 0.26 6 hr later. On the delayed scans (6 hr after In^{113m} chloride administration), the images clearly showed the presence of radioactivity in the interior of 86.4% of hepatic tumors, including 3 cases where the radioactive level at the tumoral area was higher than in the normal hepatic region. The results were doubtful in 2 cases, and in 1 case the concentration defect persisted in the left hepatic lobe. Scintigraphic images of the hepatic blood pool, obtained 10 min after i.v. administration of In^{113m} chloride permitted a differential diagnosis in 40.9% of the cases (negative results in 4.5% of the cases) as compared to a differential diagnosis with delayed images for 86.4% of the cases. The results were in doubt in 0.1% of the cases and negative in 4.5% of the cases with the delayed scan. It was concluded that liver scintigraphy with radiocolloids combined with scanning of the distribution of hepatic blood pool with In^{113m} chloride to obtain more precise information on the degree of vascularity and blood flow in the interior of intrahepatic lesions improves the possibility of reaching a differential diagnosis between tumors and other space-occupying lesions.

8441 SERUM-ALPHA$_1$-FETOPROTEIN IN HEPATOCELLULAR CARCINOMA. *(E.)* Kohn, J.; Weaver, P. C. (Queen Mary's Hosp., London, England). *Lancet* (7876): 334-337, 1974.

Sera from 2225 patients (median age 50-70 yr, male/female ratio of 3.4/1) were screened for α_1-fetoprotein (AFP) by a sensitive countercurrent immunoelectrophoretic technique. Primary hepatocellular carcinoma was present in 107 of the cases; the remaining cases were mainly hepatic disorders. Positive AFP reactions were obtained in 90 out of the 107 hepatocellular carcinoma patients, including 5 cases of hepatoblastoma. Four cases which were negative to AFP screening with immunoelectrophoresis showed significantly raised serum-AFP levels upon radioimmunoassay. Raised AFP levels, usually transient and small, were observed in 16 cases of liver disease other than hepatocellular carcinoma and in 14 cases for which diagnoses were unavailable. The frequency of false-positives was 1.8%. The immunoelectrophoretic screening test for AFP detects serum-AFP at concentrations in the 200 ng/ml range and appears to be adequate for the detection of hepatocellular carcinoma in most cases. Radioimmunoassay reveals a greater percentage of AFP-positive cases but poses problems of interpretation. Raised AFP levels after surgery or chemotherapy indicate failure of treatment, although the converse does not necessarily hold.

GASTROINTESTINAL DISEASES

ESOPHAGUS

8473 MORPHOLOGIC ASPECTS OF EXPERIMENTAL ESOPHAGEAL LYE STRICTURES. I. PATHOGENESIS AND PATHOPHYSIOLOGIC CORRELATIONS. *(E.)* Butler, II, C.; Madden, J. W.; Davis, W. M.; Peacock, Jr., E. E. (Univ. Arizona Coll. Med., Tucson). *J. Surg. Res.* 17 (4):232-244, 1974.

Esophageal lye injuries were created in 45 adult mongrel dogs by exposing a 5-cm length of esophagus to 20% sodium hydroxide at 30 cm pressure for 50 sec. During the first 2 weeks, morphological changes in the esophagus were similar in all dogs. Edema, coagulation necrosis of mucosa and submucosa, and cellulitis were observed within 48 hr. After 5 days the coagulum was replaced by edematous and inflamed granulation tissue. After 2 weeks deposition of scar collagen fibers and migration of surface epithelium from adjacent intact mucosa were evident. Changes after 2 weeks varied with the depth of injury. Of 39 surviving dogs, 9 had significant injury to the mucosa and submucosa only (Grade I), 6 had partial muscle injury (Grade II), and 24 had full-thickness injury penetrating the entire muscularis. Severe esophageal strictures (5 cm or less) were present in 17 of the 24 dogs with Grade III lesions but were absent in 7 of these dogs and in all 15 dogs with lesser injury. Thus, although stricture formation depends on full-thickness esophageal injury, such injury does not guarantee the development of stenosis. Stricture was not related to persistent mucosal ulceration, scar proliferation, or wall thickness. Stenosis resulted from an hourglass constriction of the whole esophagus in each case. Feeding patterns in dogs surviving acute burns did not correlate with size of the fixed esophagus but did correlate with the radiographic size. Functional and radiographic abnormalities were severe in some animals without significant esophageal narrowing at autopsy. Factors such as edema and peristaltic dysfunction may account for disparities between structural and functional effects of lye injury.

8474 CLINICAL AND MANOMETRIC INVESTIGATIONS OF THE LOWER ESOPHAGEAL SPHINCTER AND ITS REACTIVITY TO PENTAGASTRIN IN PATIENTS WITH HIATUS HERNIA. *(E.)* Siewert, R.; Weiser, F.; Jennewein, H. M.; Waldeck, F. (Univ. Gottingen Clin., Germany). *Digestion* 10(4/5):287-297, 1974.

Results of manometric tests on 45 patients with axial hiatus hernia correlated with the results of clinical investigation (anamnesis of reflux, HCl secretion after pentagastrin, x-rays, and esophagoscopy with biopsies). The manometric tests were 3-point manometry for measuring the reflexive pressure increase in the lower esophageal sphincter (LES) after abdominal compression and the continuous withdrawal method before and after pentagastrin injection (0.6 μg/kg i.v.). According to the results obtained by all methods, the patients could be divided into 2 groups. Group I consisted of 12 patients with a competent LES and normal reactivity to pentagastrin, no radiologic evidence of reflux, and moderate clinical symptoms. Group II comprised 33 patients with a basal LES pressure significantly below the 19.4 ± 7.3 mm Hg recorded for 20 normal controls and a lower pressure increase after pentagastrin stimulation than the control value of 29.9 ± 6.5 mm Hg. This group was also characterized by x-ray evidence of reflux (33), insufficient pressure increase in the LES after abdominal compression (29), esophagitis (17), stenosis (3), and hyperacidity (5). Based essentially on LES response to pentagastrin, group II patients could be divided into subgroup A with a normal LES response to pentagastrin (32.3 ± 8.9 mm Hg) and subgroup B with a significantly reduced response (12.8 ± 3.1 mm Hg). There was a good correlation between the abnormal pentagastrin response and the severity of the other parameters tested.

STOMACH

8490 CELLULAR SITES OF IMMUNOGLOBULINS. IV. STUDIES OF ANTRAL MUCOSA OF HUMAN STOMACHS. *(E.)* Chen, S. T.; Tobe, T. (Fac. Med., Kyoto Univ., Japan). *Digestion* 10(3):177-183, 1974.

The distribution of immunoglobulin (Ig)-containing cells in the gastric antral mucosa of 18 patients with various abnormalities of the stomach was studied by fluorescent antibody techniques. The abnormalities were chronic gastritis (5 cases), benign gastric ulcer (7), adenocarcinoma (3), undifferentiated cell carcinoma (2), and lymphosarcoma (1). The stroma under the surface epithelium and glandular crypts of the stomach were rich in plasma cells and lymphoid cells which reacted specifically with anti-IgA, anti-IgG, anti-IgM, anti-κ- or anti-λ-chain immunofluorescent agents. IgA-containing cells accounted for 58-94% (mean 76.2%) of fluorescent cells, IgM-containing cells for 3-27% (mean 13.4%), and IgG-containing cells for 3-28% (mean 10.4%). IgA type cells were diffusely scattered throughout the interstitial spaces between the crypts and in the lamina propria. IgM-containing cells tended to be concentrated in the interstitium of glands, whereas IgG-containing cells were usually found at the base of the lamina propria near the capillaries. In pyloric glands not disrupted by lesions, IgA was observed in the apical portion of epithelial cells, and IgM was seen extracellularly between the epithelial cells and in the lumen. In gastric cancer patients, IgG-containing immunocytes were visible in intermuscular spaces near the site of tumor cell invasion beneath the cancers. Malignant cells in 1 patient with undifferentiated cell carcinoma and in the patient with lymphosarcoma appeared to react with anti-IgG or anti-IgM. Immunoglobulins have not been previously identified on cancer cells in gastrointestinal tissue.

8491 GASTRIC PHYCOMYCOSIS. *(E.)* Lawson, H. H.; Schmaman, A. (Baragwanath Hosp., Johannesburg, South Africa). *Br. J. Surg.* 61(9):743-746, 1974.

A study was made of 9 patients, 7 with invasive gastric phycomycosis (1 infant, 5 men and 1 woman, aged 4 months to 50 yr) all of whom died, and 2 men (aged 33 and 41 yr) with superficial colonization only. Four cases of invasive fungal infection came to surgery with preoperative diagnoses of peritonitis (1) or perforation of a hollow viscus (3). A perforated gastric ulcer was found in each of these 4 cases and 2 had associated duodenal ulcers. The 2 patients in whom the fungus colonized the gastric mucosa without deeper invasion of the blood vessels had histories of 1 yr or more of dyspepsia. They presented with features of peritonitis or perforation, and were operated on for bleeding. A definite distinction between invasion and colonization can only be made histologically. However, invasion should be suspect at operation by the hardness of the tissues, by their black discoloration and a hyperemic zone between normal and abnormal areas. The fungus can invade the mucosa through a chronic gastric ulcer, where it usually occurs in relation to the lesser curvature, or as a result of ulceration occurring anywhere in the stomach during the course of a debilitating disease. In these 7 cases of invasive infection, the main problem was severe superimposed infection occurring as a result of leakage from the stomach, indicating poor general health in the presence of phycomycosis infection. Colonization does not apparently affect wound healing. If the patient is fit and phycomycosis is suspected, a partial gastrectomy should be carried out to remove the necrotic tissue. Amphotericin B therapy, potassium iodide in large doses, antibiotics to combat secondary bacterial infection, and cortisone are useful. Cephaloridine and gentamicin have been effective as an antibiotic combination. The type of lesion and the presence or absence of a severe underlying debilitating disease are the determining factors in the outcome of the disease.

8492 ACUTE GASTRODUODENAL DISEASE AFTER THERMAL INJURY. AN ENDOSCOPIC EVALUATION OF INCIDENCE AND NATURAL HISTORY. *(E.)* Czaja, A. J.; McAlhany, J. C.; Pruitt, Jr., B. A. (Brooke Army Med. Ctr., Fort Sam Houston, Tex.). *N. Engl. J. Med.* 291(18):925-929, 1974.

Early and serial endoscopic examinations of the stomach and duodenum were performed in 32 burn patients (31 men and 1 woman, aged 16-74 yr) to determine the incidence and natural history of acute gastroduodenal disease after thermal injury. The burn size varied from 23 to 96% of the body with the average size at 56.6% of body surface. Mortality was 75%. A total of 53 examinations were performed, the earliest at 12 hr after injury. Gastric erosions were noted in 25 of 29 patients with large burns. Seventeen of 23 (74%) had lesions within 72 hr after the burn. A gastric ulcer developed in 7 patients (22%). Ulcerations occurred only in diffusely abnormal areas and were not discovered before 72 hr after the burn. Duodenal ulceration was present in 9 patients (28%); all but 1 had concomitant gastric disease. In 2 cases, an ulcer evolved from an erosive duodenitis. The early development, morphology, and histology of the lesions suggested ischemic damage of the mucosa. These results indicate that acute gastroduodenal disease does develop in the majority of patients soon after thermal injury and that it frequently remains clinically inapparent. The early and frequent involvement of both stomach and duodenum indicate a common susceptibility to the initial insult. Serial endoscopic evaluations in 15 patients indicated that, although mucosal damage did occur early, the behavior of this mucosal injury was influenced by the nature of the patient's subsequent course. The 9 patients whose clinical course deteriorated with the onset of sepsis, hypotension, or respiratory insufficiency had progression of mucosal disease. Perforation or gastrointestinal hemorrhage requiring more than 3 U of blood replacement over 24 hr occurred mainly in patients with ulcers of the stomach or duodenum (8 of 9). Bleeding from erosive gastritis was rarely life threatening.

8493 EFFECTS OF PROXIMAL GASTRIC VAGOTOMY ON INTRAGASTRIC PRESSURE AND ADAPTATION IN PIGS. *(E.)* Stadaas, J; Aune, S; Haffner, J. F. W. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(5): 479-485, 1974.

The intragastric pressure/volume relation was studied in 6 anesthetized pigs with a large plastic bag placed in the stomach. Basal pressure, rhythmic activity and the time required for the basal pressure to stabilize after each alteration in volume (adaptation time), were studied after stepwise filling and emptying of the bag. Studies were made in the normal state, after proximal gastric vagotomy, and following additional truncal vagotomy. Three pigs serving as controls were studied twice: after laparotomy and after sham operation. After proximal gastric vagotomy, basal pressure increased significantly more with distention than before. A significant increase in adaptation time was noted as well as a marked reduction of rhythmic activity. Truncal vagotomy had no additional effects on the parameters in the present series. The lack of significant changes following additional truncal vagotomy indicates that extragastric vagal reflexes and vagal innervation to the distal part of the stomach seem of little importance for the basal pressure and volume adaptation. The motility disturbances noted after proximal gastric vagotomy may be partly due to devascularization, since proximal gastric vagotomy implies ligation of vessels combined with sectioning of cholinergic as well as adrenergic nerves to the lesser curvature. The reduction in rhythmic activity presumably results from reduced contractile activity in the proximal parts of the stomach. Rapid emptying of liquids by a rapidly increasing intragastric pressure may be the effect of proximal gastric vagotomy if the present findings apply to man.

8494 THE INFLUENCE OF TOTAL GASTRECTOMY ON SURVIVAL IN MALIGNANT ZOLLINGER-ELLISON TUMORS. *(E.)* Fox, P. S.; Hofmann, J. W.; Decosse, J. J.; Wilson, S. D. (Med. Coll. Wisconsin, Milwaukee). *Ann. Surg.* 180(4):558-566, 1974.

The effect of total gastrectomy on the biologic behavior of malignant gastrinomas was studied from patient data in the Zollinger-Ellison tumor registry. A total of 267 patients with documented metastatic tumor had definitive gastric operations. In the 137 patients who had total gastrectomy, survival was 75% at 1 yr, 55% at 5 yr, and 42% at 10 yr. In the 130 patients who had lesser gastric operations, survival was 51% at 1 yr, 27% at 5 yr, and 18% at 10 yr. Deaths from progressive tumor growth occurred in 17% of the 119 patients at risk after total gastrectomy and in 30% of the 91 patients at risk after lesser gastric operations. A subgroup of 127 patients with documented liver metastasis had definitive gastric operations. In the 73 patients who had total gastrectomy, survival was 68% at 1 yr, 42% at 5 yr, and 30% at 10 yr. In the 54 patients who had lesser gastric operations, survival was 44% at 1 yr, 7% at 5 yr, and none at 10 yr. Deaths from progressive tumor growth occurred in 25% of the 64 patients at risk after total gastrectomy and 50% of the 36 patients at risk after lesser gastric operations. Regression of metastatic Zollinger-Ellison tumor was documented in only 4 patients, all of whom had total gastrectomy. Presumptive regression of primary tumor occurred in 7 patients, 5 of whom had total gastrectomy. The data demonstrate that total gastrectomy is the procedure of choice for malignant Zollinger-Ellison tumors, even in the presence of widespread metastasis. The results for total gastrectomy indirectly support the concept of a gastric influence on tumor growth; however, the results also show that total gastrectomy does not provide permanent or predictable protection against subsequent tumor growth and metastasis.

8495 INHIBITORY EFFECTS OF L-GLUTAMINE ON THE ASPIRIN-INDUCED GASTRIC LESIONS IN THE RAT. *(E.)* Okabe, S.; Takeuchi, K.; Nakamura, K.; Takagi, K. (Fac. Pharmaceut. Sci., Univ. Tokyo, Japan). *J. Pharm. Pharmacol.* 26(8):605-611, 1974.

STOMACH

Peptic Ulcers

8515 INHIBITION OF GASTRIC ACID SECRETION AND ULCER FORMATION IN THE RAT BY ORALLY-ADMINISTERED 11-DEOXYPROSTAGLANDIN ANALOGUES: 15-HYDROXY-16,16-DIMETHYL-9-OXOPROST-5,13-DIENOIC ACIDS. *(E.)* Lippmann, W. (Biochem. Pharm. Dept., Ayerest Lab., Montreal, Canada). *Prostaglandins* 7(3):231-246, 1974.

The 11-deoxyprostaglandin analogue 15(nat)-hydroxy-16,16-dimethyl-9-oxoprost-5,13-dienoic acid (AY-24,609) effectively inhibited gastric acid secretion and ulcer formation in the rat when administered p.o. (0.2 ml in 0.2% carboxymethyl cellulose). In comparison with the structurally related 15-hydroxy-15-methyl-9-oxoprostanoic acid (AY-22,469), AY-24,609 was 8.7 times more potent in inhibiting basal acid secretion and 9.0 times more potent in inhibiting pylorus ligation-induced ulcers in female albino rats. In male albino rats, AY-24,609 was 4.8 times more potent than AY-22,469 in inhibiting ulcer formation induced by indomethacin (0.5 ml i.p.). The median effective dose for causing diarrhea in the 24-hr fasted rat was 7 mg/kg for AY-24,609 and 140 mg/kg for AY-22,469. The analogue 15(epi)-hydroxy-16,16-dimethyl-9-oxoprost-5,13-dienoic acid (AY-24,696) was less active than AY-24,609. In comparison with AY-22,469, its relative potencies for the above activities were 0.6, 1.6, and 2.5, resp. The median effective dose for producing diarrhea was 49 mg/kg. In general, gastric juice volume was not altered by AY-24,609 and AY-22,469. Both analogues appear to be potentially useful therapeutic agents for treatment of gastric hypersecretion and peptic ulcers.

8516 RESTING GASTROESOPHAGEAL SPHINCTER PRESSURE IN PATIENTS WITH GASTRIC OR DUODENAL ULCER. *(E.)* Csendes, A.; Acevedo, J. C. (Jose Joaquin Aguirre Hosp., Univ. Chile, Santiago). *Digestion* 10(4-5):282-286, 1974.

Resting gastroesophageal sphincter pressure was measured with continuously perfused catheters in 40 control subjects (23 men and 17 women, aged 19-68 yr), in 21 patients (10 women and 11 men, aged 23-65 yr) with benign gastric ulcer, and in 26 patients (18 men and 8 women, aged 22-69 yr) with duodenal ulcer. Gastric acid secretion was also determined. No significant differences in resting sphincter pressure were noted in any group. Spontaneous gastric output was similar among normals and gastric ulcer patients, but duodenal ulcer patients secreted more acid during the basal period than did controls. The maximal acid output after histamine (0.04 mg/kg) was significantly reduced in gastric ulcer patients when compared to controls or to duodenal ulcer patients. No correlation between resting gastroesophageal sphincter pressure and basal secretion of acid or between resting gastroesophageal sphincter pressure and maximal acid output was found for any group separately or for all 3 groups combined.

8517 ULCER DISEASE, METABOLIC ALKALOSIS AND HYPERPARATHYROIDISM: A MECHANISM OF INTERRELATIONSHIP? *(E.)* Kaplan, E. L.; Peskin, G. W.; Deveney, C.; Way, L.; Jaffe, B. (Univ. Chicago Hosp., Ill.). *Ann. Surg.* 180(4):549-557, 1974.

The effects of sodium bicarbonate (300 mEq, 3.6-5.8 mEq/kg) infused i.v. over a 90-min period were studied in 5 normocalcemic controls and 5 patients with primary hyperparathyroidism. In each control infusion induced a typical hypokalemic, hypochloremic metabolic alkalosis. Arterial pH increased from 0.06 to 0.14 U. Mean serum calcium concentration decreased 1.2 mg/100 ml during the 90-min period; serum ionized calcium, determined in 1 subject, decreased 1.2 mg/100 ml. The mean parathyroid hormone concentration increased from 35 μl-Eq/ml (basal) to 112 μl-Eq/ml at 75 min. Serum gastrin did not change significantly during infusion although gastric acid secretion decreased in 4 of the 5 subjects. Of the 5 patients with hyperparathyroidism, 4 had multiglandular disease and only 1 appeared to have a single adenoma. In response to bicarbonate infusions, arterial pH in this group increased from 0.11 to 0.19 U. Total calcium concentration decreased in each patient, the maximal mean decrease in serum calcium of 1.4 mg/100 ml occurring at 60 min. The mean basal parathyroid hormone concentration of 170 μl-Eq/ml increased to 289 μl-Eq/ml 60 min after the start of the infusion. Mean gastrin concentrations were normal in these subjects and did not change during induction of alkalosis. The cycle of metabolic alkalosis, depressed serum ionized calcium concentration, and parathyroid stimulation demonstrated in this study may represent a major mechanism in the etiology of parathyroid disease associated with severe peptic ulcer disease and Zollinger-Ellison tumors. The data also indicate that sodium bicarbonate is a safe and effective agent for release of parathyroid hormone.

8518 THE CARBOHYDRATE AND ESTER SULFATE CONTENT OF MUCOSAL BIOPSIES IN HEALTH AND IN PA-

TIENTS WITH DUODENAL ULCER. *(E.)* Andre, F.; Bouhours, D.; Andre, C.; Descos, F.; Lambert, R. (Edward Herriot Hosp., Lyon, France). *Clin. Chim. Acta* 56(3):255-259, 1974.

The carbohydrate and ester sulfate content of duodenal mucosal biopsies from 11 patients with duodenal ulcer and from 11 control subjects were determined by gas-liquid chromatography. The net amounts and molar ratios (to glucosamine) were similar in both groups. The composition of duodenal biopsies expressed as percent of dry material for duodenal ulcer patients were: N-acetylglucosamine, 2.42; N-acetylgalactosamine, 2.26; fucose, 1.89; galactose, 1.89; mannose, 2.98; glucose, 0.40; glucose, 2.50; and sulfate, 0.70. The lack of any quantitative or qualitative difference in glycoprotein components between the two groups of subjects suggests that sulfated glycoproteins, which inhibit the proteolytic activity of pepsin, are not involved in the pathogenesis of duodenal ulcer.

SMALL INTESTINE

8543 TAUROCHOLATE METABOLISM IN PATIENTS WITH SMALL INTESTINAL STAGNANT LOOPS. *(E.)* Arnesjo, B.; Sorbris, R.; Kock, N. G. (Univ. Hosp., Lund, Sweden). *Scand. J. Gastroenterol.* 9(6):579-585, 1974.

Tracer doses of ^{35}S-tauro-7-^{3}H-cholate were given to 11 patients (7 women and 4 men, aged 14-70 yr), 3 with duodenal or jejunal diverticula without malabsorption, 4 with proximal stagnant loops and malabsorption, and 4 with distal stagnant loops and slight malabsorption. Duodenal aspirates obtained during the following 2 days were examined. Specific radioactivities of both isotopes were determined. Patients with proximal blind loops without malabsorption had a taurocholate metabolism no different from healthy individuals. Patients with stagnant loop syndromes, regardless of the location of the lesions, had diminished taurocholate pool sizes, increased turnover of taurocholate, increased taurocholate synthesis, and increased rates of deconjugation and, provided an intact colon was present, increased rates of 7-α-dehydroxylation. In 4 cases the administered isotopes disappeared too rapidly to allow accurate estimation of their taurocholate metabolism. In 4 patients with ileostomy-reservoir after panproctocolectomy, low duodenal bile acid concentrations were found with virtually no deoxycholate, whereas the glycine/taurine bile acid molar ratios were normal. The remaining patients with stagnant loop syndromes had normal duodenal bile acid concentrations, increased glycine/taurine molar ratios, and normal trihydroxy/dihydroxy molar ratios. These results indicate that patients with stagnant loops and malabsorption have increased taurocholate turnover, with increased rates of bacterial modification of taurocholate yielding higher concentrations of free bile acids by an increased rate of deconjugation in the intestine. This finding, coupled with the increased rate of measurable 7-α-dehydroxylation, indicates a larger proportion of the free bile acids present in the small intestinal lumen of these patients, consisting of the more toxic secondary bile acids, deoxycholic or lithocholic acid.

8544 SMALL BOWEL IN IMMUNOGLOBULIN DEFICIENCY SYNDROMES. *(E.)* Marshak, R. H.; Hazzi, C.; Lindner, A. E.; Maklansky, D. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):227-240, 1974.

Immunoglobulin deficiency syndromes with gastrointestinal manifestations may be primary or secondary to some other disease involving the gastrointestinal tract. The primary disorders can be classified as variable immunoglobulin deficiency, comprising the majority of patients with immunodefciency, and selective IgA deficiency. The 3 subcategories of variable immunoglobulin deficiency are (1) hypogammaglobulinemic sprue; (2) hypogammagloublinemia with pernicious anemia and atrophic gastritis; and (3) dysgammaglobulinemia with nodular lymphoid hyperplasia of the small intestine and giardiasis. Selective IgA defiency includes: (1) IgA deficient sprue with gluten enteropathy, villous atrophy, and presence of ample plasma cells in the lamina propria; and (2) IgA deficiency with nodular lymphoid hyperplasia of the small intestine (uncommon). Secondary disorders comprise: (1) decreased immunoglobulin synthesis and/or increased synthesis of abnormal immunoglobulins (e.g., plasma cell dyscrasias including Waldenstrom's macroglobulinemia and alpha-chain disease, lymphosarcomas, chronic lymphatic leukemia); (2) increased immunoglobulin breakdown and loss (e.g., exudative gastroenteropathies, intestinal lymphangiectasia); and (3) amyloidosis. Based on this classification, the small intestine roentgen features associated with the various immunoglobulin disorders are (1) the sprue pattern, as in hypogammaglobulinemic sprue and in IgA deficient sprue; (2) multiple nodular defects, as in dysgammaglobulinemia and lymphoma; (3) inflammatory changes secondary to giardiasis; and (4) thickening of small intestinal folds, as in amyloidosis, lymphoma, macroglobulinemia, plasma cell dyscrasias, and intestinal lymphangiectasia.

8545 THE SIGNIFICANCE OF BILE ACIDS AND ALDOSTERONE FOR THE ELECTRICAL HYPERPOLARIZATION OF HUMAN RECTUM IN OBESE PATIENTS TREATED WITH INTESTINAL BYPASS OPERATION. *(E.)* Rask-Madsen, J.; Bruusgaard, A.; Munck, O.; Nielsen, M. D.; Worning, H. (Glostrup Hosp., Denmark). *Scand. J. Gastroenterol.* 9(5):417-426, 1974.

The effects of jejunoileal bypass on the rectal potential difference and the transepithelial transport of electrolytes and water in the rectum and colon were investigated in 10 morbidly obese patients (9 women and 1 man, aged 24-46 yr). Transport rates of electrolytes and water were measured pre- and postoperatively by *in vivo* dialysis of rectal fluids and by steady-state perfusion of whole colon. Plasma aldosterone and renin were measured radioimmunochemically, simultaneously with exchangeable sodium and total body potassium, to evaluate whether a state of secondary hyperaldosteronism due to electrolyte derangement existed postoperatively. A semiquantitative determination of fecal bile salts was made after chromatographic separation since di- and trihydroxy bile salts interfere with colonic ion transport. A significant increase in potential difference was noted postoperatively, (from -45 to -64 mV). The mucosa to serosa flux of sodium and net transport rates of chloride and water also increased significantly when physiochemical environments in the rectal lumen were unaffected by the procedures of measurement. However, normal values were obtained when the colon was perfused with isotonic saline. Plasma aldosterone and plasma renin decreased postoperatively in accordance with the findings of potassium depletion. A marked decrease in the concentrations of secondary bile salts (deoxycholic acid and lithocholic acid) was observed also. The hyperpolarization and alterations in transepithelial transport of salt and water in shunt-operated patients are probably not the result of mineralocorticoid stimulation but are probably due to disappearance of dihydroxy bile salts from the colonic lumen.

8546 OBSTRUCTION OF THE DUODENUM BY THE SUPERIOR MESENTERIC ARTERY - DOES IT EXIST IN CHILDREN? *(E.)* Burrington, J. D.; Wayne, E. R. (Children's Hosp., Denver, Colo.). *J. Pediatr. Surg.* 9(5):733-741, 1974.

A series of 20 children (9 boys and 11 girls, aged 1 month to 19 yr) with superior mesenteric artery syndrome was studied. The causes of duodenal compression in these cases included rapid growth without a proportiante weight gain (10); congenital defects (2); esophageal burn (1); weight loss (3, all boys losing weight to qualify for athletic teams); scleroderma (1); spine fusion (1); colitis (1); and leukema (1). Factors predisposing a patient to this syndrome include a high, tight ligament of Trietz, abnormally high position of the third portion of the duodenum, unusual take-off of the superior mesenteric artery from the aorta, and perhaps, the relation of the aorta to the lumbar vertebral bodies. The patient usually has an asthenic build, severe postprandial pain and bloating, and bilestained vomiting early in the disease. Radiological factors include dilatation of the proximal duodenum, obstruction to the flow of barium just to the right of the vertebral column, and diminished gas in the remainder of the bowel. In some of these patients the duodenum crossed at the level of the L_2, but in most the duodenum crossed in the lower, more normal position. In most, the entire 2nd portion of the duodenum was posterior to the vertebral column. Fluoroscopy revealed marked to-and-fro churning by the duodenum with retrograde peristalsis sufficiently vigorous to pass a large bolus of barium back into the stomach. Often lying prone on the left side or assuming the knee-chest position will offer symptomatic relief. If rapid emptying can be achieved by assuming these positions, nonoperative therapy will be sufficient. Findings at operation include the marked dilatation of the 2nd portion of the duodenum with distinct narrowing at the point where the duodenum passes beneath the mesentery through its retroperitoneal attachments, and a tight, rigid tunnel to the right of the spine where the duodenum passes beneath the mesentery. The operation proposed in this series called for removal of the source of entrapment rather than bypassing it and does not involve opening the bowel. The 8 patients on whom this procedure was performed had minimal morbidity and left the hospital eating a normal diet. No gastric ulcers were found in this series.

SMALL INTESTINE

Malabsorption

8573 FAT ABSORPTION IN INFANTS OF BIRTH WEIGHT LESS THAN 1,3000 gm. *(E.)* Katz, L.; Hamilton, J. R. (Fac. Med., Univ. Toronto, Canada). *J. Pediatr.* 85(5):608-614, 1974.

Fat absorption was studied during the first 2 months of life in 15 infants with birth weights less than 1300 g. The actual fat content of the formula fed to the infants at the standard dilution was 3.70 ± 0.31 g/100 ml. The capacity to absorb fat was mildly impaired at 2 weeks (75% of intake) but was significantly improved at 2 months (88.4% of intake), approaching that of the adult. In 5 infants given p.o. calcium supplements (147 mg/kg/day) starting at age 3 weeks, fat excretion at 6-8 weeks was significantly greater than in nonsupplemented infants. At 2 weeks and 2 months, a fatty meal was administered through stomach tube and specimens of duodenal juice were obtained; the meal contained 2.5 g corn oil or triolein, 0.25 g lecithin, and 1 g/100 ml polyethylene glycol in a volume of water to equal the routine feeding. The pH of most samples fell within a narrow alkaline range. Polyethylene glycol and bilirubin concentrations were similar in both collection periods. Total intraluminal bile salt concentrations were generally low at 2 weeks but had increased at 2 months; maximum postprandial bile salt concentrations were significantly correlated with fat excretion. Glycine conjugates were minimal at 2 weeks and greatly increased at 2 months. Free bile acids were scarely detectable in either period, while lipase activity and mono- and diglycerides were consistently present in duodenal contents. Three infants had appreciable quantities of triglycerides at 2 weeks. The data indicate the need for care in determining the appropriate dietary fats and fat-soluble vitamins for early nutirition of low birth weight-infants.

8574 THE EXPERIMENTAL PRODUCTION OF VITAMIN B_{12} DEFICIENCY IN THE BABOON (Papio cynocephalus). A 2-YEAR STUDY. *(E.)* Siddons, R. C. (Wellcome Trust Res. Lab., Nairobi, Kenya). *Br. J. Nutr.* 32(2):219-228, 1974.

The development of vitamin B_{12} deficiency, as indicated by the serum and liver vitamin B_{12} levels and the excretion of methylmalonic acid, was studied over a 2-yr period in 15 male baboons (*Papio cynocephalus*) given a diet deficient in vitamin B_{12}. The effects of partial hepatectomy and the inclusion of either ampicillin or sodium propionate in the diet on the rate of development of the deficiency were also studied. Basal serum B_{12} levels in animals fed primarily a vegetarian diet were less than 100 ng/liter and the mean liver vitamin B_{12} concentration was 0.56 μg/g. Similar serum and liver vitamin B levels were found in baboons given a purified diet supplemented with 1 μg vitamin B_{12}/day, and marked increases in the serum and liver vitamin B_{12} levels occurred when the daily intake was increased to 2 μg. The serum vitamin B_{12} levels decreased to less than 20 ng/liter in all baboons given a vitamin B_{12}-deficient diet. The liver vitamin B_{12} concentration also decreased in all baboons given a deficient diet. At 9 months the lowest levels (0.20 μg/g) were found in partially hepatectomized baboons but subsequently baboons given the diet containing ampicillin had the lowest levels (0.11 μg/g). The excretion of methylmalonic acid after a valine load was found to be inversely related to the liver vitamin B_{12} concentration. In the early part of the study, partially hepatectomized baboons excreted the highest amount but subsequently baboons given a diet containing ampicillin excreted the highest amount. Increased foriminoglutamic acid excretion after a histidine load was observed in 2 baboons given a vitamin B_{12}-deficient diet and in both baboons the liver folic acid concentration was low. No hematological or neurological symptoms of the vitamin B_{12} deficiency were observed.

8575 INTRACTABLE MALABSORPTION WITH A FLAT JEJUNAL MUCOSA AND SELECTIVE IgA DEFICIENCY: A CASE REPORT WITH IMMUNOLOGICAL AND AUTORADIOGRAPHIC STUDIES. *(E.)* Anderson, K. E.; Finlayson, N. D. C.; Deschner, E. E. (Cornell Univ. Med. Ctr., New York, N.Y.). *Gastroenterology* 67(4):709-716, 1974.

The case history of a 13-yr-old boy with selective immunoglobuoin A (IgA) deficiency, flat jejunal mucosa, and fatal malabsorption is reported. No IgA was detectable in serum, saliva, or jejunal fluid. The patient did not respond to a gluten-free diet, to a course of tetracycline, neomycin, sulfisoxazole, and metronidazole, or to supplementary p.o. medium-chain triglycerides, amino acids, and pancreatic enzymes. The mucosal lesion was the only basis demonstrated for malabsorption; giardiasis and bacterial overgrowth were not present. I.v. infusion of fresh-frozen plasma (> 10 cc/kg) increased serum IgA levels to 14.5-16.00 mg/100 ml over a 30-day period. Thereafter, the IgA level declined, deterioration resumed and the patient eventually died of an air embolus after insertion of a subclavian venous catheter. Investigation of jejunal mucosa after incubation with ^{3}H-thymidine showed very rapid proliferation of the small intestinal epithelium, as in gluten-sensitive enteropathy, with active mitosis and DNA synthesis not only in the crypts but also on the surface mucosa. This case indicates that a patient with gluten enteropathy and selective IgA deficiency may not respond to plasma infusions.

8576 TRANSIENT MALABSORPTION IN INFECTIOUS MONONUCLEOSIS: CASE REPORT. *(E.)*

Butler, M. L.; Carlton, L.; DeGreen, H. P.; Teplick, S. K.; Metz, J. R. (Tripler Army Med. Ctr., Honolulu, Hawaii). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):241,244, 1974.

A 19-yr-old boy with infectious mononucleosis and diarrhea, usually preceded by abdominal cramps, was found to have malabsorption. Clinical and biochemical findings included: d-xylose excretion (25 g oral load), 2 g in 5 hr; 72 hr stool fat, 32 g; stools, guaiac-negative, negative for ova and parasites; duodenal aspirate, no pathogens. Roentgenology showed thickening of the mucosal folds throughout the small bowel. A jejunal biopsy showed blunting of some villi with infiltration of the lamina propria by atypical lymphocytes. Over a 16-week period the diarrhea was resolved without drug or dietary therapy; all parameters of small bowel function returned to normal, and a repeat biopsy was normal.

8577 HL-A8 AND HAPLOTYPE HL-A1-8 IN COELIAC DISEASE. *(E.)*

Ludwig, H.; Granditsch, G.; Polymenidis, Z. (Immunol. Inst., Univ. Vienna, Austria). *J. Immunogenet.* 1(2):91-97, 1974.

The transmission of human lymphocytes antigen-8 (HL-A8) and HL-A1 and of the haplotype HL-A1-8 within families with celiac children was investigated by segregation analysis. The study involved 54 patients (21 boys and 33 girls, aged 6 month to 14 yr with one aged 23 yr), 30 (56%) with HL-A8 and 31 (57%) with HL-A1. Corresponding percentages for the control group of 240 unrelated individuals were 16 and 29%, resp. The increase in HL-A1 frequency was attributed to linkage disequilibrium between the genes involved. The haplotype HL-A1-8 frequency was also significantly increased in celiac children. A slightly lower frequency of HL-A3 in the 1 locus and a low frequency of HL-A7 in the 2 locus in celiac children may have been a consequence of the high frequency elevation of HL-A8 and HL-A1 leading to reduced frequencies of other HL-A antigens. In family studies, 90 parents and 34 healthy siblings of 47 celiac children had HL-A antigens. In all but 2 of these cases the parents and siblings were free of clinical symptoms. Haplotype HL-A1-8 was found in 22 of these 47 (47%) celiac children. In the control group the haplotype HL-A1-8 frequency was 6.7%. Tissue typed siblings of the celiac patients, though free of clinical symptoms, possessed haplotype HL-A1-8 in 35%. Parents also had increased haplotype HL-A1-8: 35.5% in mothers and 24.4% in fathers. Segregation analysis was performed in families where 1 parent was heterozygous for an antigen and the other was negative. This analysis revealed a deviation from the expected distribution of the single antigens HL-A8 and HL-A1 in celiac children while an almost even distribution of these antigens was noted in healthy siblings. In the few haplotypes frequent enough to be included in the segregation analysis, a similar deviation from the expected distribution was found for HL-A1-8 in celiac patients again in contrast to the almost even distribution observed in their healthy siblings. These results indicate a genetic mechanism involved in the pathogenesis of celiac disease. The gene(s) partly responsible for the development of the disease seem preferentially linked to HL-A8.

8578 NECROPSY STUDIES ON ADULT COELIAC DISEASE. *(E.)*

Thompson, H. (Gen. Hosp., Birmingham, England). *J. Clin. Pathol.* 27(9):710-721, 1974.

The distribution of mucosal changes in adult celiac disease was studied in 24 cases within 4 hr of death. Six patients on a gluten-containing diet showed a flat mucosa in the jejunum, convolutions and ridges in the middle 1/3 of the small intestine, and digitate and leaf villi in the distal 1/3. In 1 case, flat mucosa involved 2/3 of the jejunum and low convolutions were present in the distal 1/3. Of 18 patients treated with a gluten-free diet, 11 had responded well clinically and histologically and 6 of these had no evidence of flat mucosa. Recticulum cell sarcoma was demonstrated in 10 patients, including 3 who had been on a gluten-free diet for 4, 9, and 15 yr, resp., with a good response. The primary site was the small intestine in 7 cases (jejunum 2, mid-ileum 4, terminal ileum 1), stomach in 1, and lymph nodes in 2. There were 7 cases each of multiple lesions in the gastrointestional tract and of metastases. Ulceration of the small intestine was present in 5 cases and was a fatal complication in 2. Other complications of celiac disease were nonobstructing mucosal diaphragms (4 cases), brownish pigmentation of the small intestine (9), fatal volvulus (2), ulcerative colitis (1), lymphoreticular atrophy (10), nonspecific recurrent skin eruption (2), and bronchopneumonia (11). The high incidence of neoplasia in this series supports the view that malignancy is a fatal complication of adult celiac disease. In particular, the 10 cases of recticulum cell sarcoma suggest a defect in the immune surveillance mechanism or viral oncogenesis.

8579 COELIAC DISEASE AND MALIGNANCY. *(E.)*

Barry, R. E. (Roy. Infirm., Bristol, England). *Tijdschr. Gastroenterol.* 16(1):23-34, 1973.

Jejunal mucosal dynamics were studied in 18 patients with subtotal villous atrophy who presented with malabsorption. All had been diagnosed as having celiac disease. Ten of the patients responded to a gluten-free diet while 8 failed to respond. Compared with the gluten-responsive group, the gluten-nonresponsive group had a markedly decreased epithelial cell turnover rate and a significant decrease in mucosal thickness. The mitotic index was also lower in the nonresponsive group, but the difference was not significant. Of the 8 patients who did not respond to a gluten-free diet, 2 were found to have lymphosarcoma of multifocal origin arising in the small intestine, 2 developed primary reticulosarcomas after their small intestine mucosal architecture had returned to normal following prednisone treatment, 1 died of a primary peritonitis, and 1 developed recurrent anemia. Laparotomy in the last case revealed focal reticulum cell-type malignancy in mesenteric lymph nodes. The results indicate that the mechanism which produces mucosal abnormality in gluten-nonresponsive patients with subtotal villous atrophy is different from that of uncomplicated celiac disease. The association of subtotal villous atrophy with a low epithelial cell turnover suggests a grave prognosis.

8580 COMPARISON OF FREE AMINO ACIDS AND DIPEPTIDE ABSORPTION IN THE JEJUNUM OF SPRUE PATIENTS. *(E.)* Adibi, S. A.; Fogel, M. R.; Agrawal, R. M. (Montefiore Hosp., Pittsburgh, Pa.). *Gastroenterology* 67(4):586-591, 1974.

Jejunal absorption of free glycine and glycylglycine were measured with a marker perfusion technique in 5 healthy men (aged 20-26 yr) and 3 women (aged 25-72 yr) with an intestinal lesion resembling sprue. Absorption rates of both free glycine and glycylglycine were markedly reduced in the sprue patients, the reduction being more severe for free glycline than for glycylglycine (15-fold decrease *versus* 4-fold). The differences between controls and sprue patients were many times greater than the individual variations due to differences in age, sex, and body weight. In each patient, the glycine absorption rate was significantly greater from a test solution containing 30 mM glycylglycine than from a test solution containing a similar amount of glycine in the free form (100 mM). In 2 additional sprue patients (a 31-yr-old man and a 16-yr-old girl), the jejunal absorption rates of glycylglycine and glycyl-L-leucine were compared. Although the absorption rates were markedly reduced compared with control values, the reduction was similar for both dipeptides. Two patients improved on a gluten-free diet but 2 developed malnutrition and required a course of steroid therapy. Repeat studies on 1 of the latter showed that posttreatment absorption rates of free glycine and glycylglycine were within the normal range. These results indicate that dipeptide is superior to free amino acid as a substrate for amino acid absorption even when the membrane transport is markedly reduced. Further, the reduction in transport involves equally a dipeptide with a poor potential (glycylglycine) and a dipeptide with an excellent potential (glycyl-L-leucine) for hydrolysis by mucosal enzymes.

8581 FOLIC ACID AND HEXOSE ABSORPTION IN SPRUE. *(E.)* Gerson, C. D.; Cohen, N.; Brown, N.; Lindenbaum, J.; Hepner, G. W.; Janowitz, H. D. (Mt. Sinai Sch. Med., New York, N.Y.). *Am. J. Dig. Dis.* 19(10):911-919, 1974.

Folic acid (pyteroylglutamic acid, PGA) absorption and hexose absorption in 7 patients with celiac sprue and 2 with tropical sprue were studied with a triple-lumen intestinal perfusion technique. Folate malabsorption was demonstrable only during perfusion with glucose or galactose and saline, not with saline alone. In 5 patients with untreated celiac sprue, PGA (25 ng/ml) absorption ranged from 5.6-16.7% with saline perfusion and 0-13.3% with saline and hexose. Three of 5 patients perfused with hexose + saline had net secretion of water and sodium into the lumen, while 3 of 4 perfused with saline alone had net secretion of water and either net secretion or almost zero net flux of sodium. In 5 controls without gastrointestinal disease, sugar had a stimulating effect on PGA and on water and sodium transport. Glucose absorption, measured in 3 patients, ranged from 0-18.9% compared with a mean of 86.0% for 11 controls. Galactose absorption was 5% in the 2 patients tested compared with control values of 53, 64, and 83%. In 2 patients treated with a gluten-free diet for 6 and 8 yr, resp., the response to glucose was normal: PGA, water, sodium, and glucose absorption were in the control range. The 2 patients with tropical sprue had a milder absorptive defect than patients with celiac sprue. Reduced transport of water, sodium, and PGA (100 ng/ml) was evident only during glucose perfusion even though glucose was better absorbed than in celiac sprue. Treatment of tropical sprue with tetracycline (250 mg 4 times/day) and folic acid (5 mg/day) resulted in partial improvement in 1 patient, while treatment for 6 months in the other restored normal absorptive function. Hexose absorption was significantly correlated with PGA absorption when treated subjects were included, but not when treated subjects were excluded.

8582 MALABSORPTION OF THIAMIN IN FOLATE-DEFICIENT RATS. *(E.)* Howard, L.; Wagner, C.; Schenker, S. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *J. Nutr.* 104(1):1024-1032, 1974.

8583 INTESTINAL ABSORPTION OF CYSTINE AND CYSTEINE IN NORMAL HUMAN SUBJECTS AND PATIENTS WITH CYSTINURIA. *(E.)* Silk, D. B. A.; Perrett, D.; Stephens, A. D.; Clark, M. L.; Scowen, E. F. (St. Bartholomew's Hosp., London, England). *Clin. Sci. Mol. Med.* 47(4):393-397, 1974.

8584 SMALL BOWEL DISEASE AND SERUMGASTRIN. *(E.)* Gillberg, R.; Stockbrugger, R.; Lundquist, G.; Dotewall, G. (Sahlgrenska Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 9(27):43, 1974.

LARGE INTESTINE

8604 CONTROLLED CLINICAL TRIAL OF MEPIPRAZOLE IN IRRITABLE BOWEL SYNDROME. *(E.)* Dotevall, G.; Groll, E. (Sahlgren's Hosp., Univ. Goteborg, Sweden). *Br. Med. J.* 4(5935):16-18, 1974.

The clinical effect of the psychotropic drug, mepiprazole (5 mg), which has pronounced tranquillizing properties but no sedative action, in the treatment of the irritable bowel syndrome was studied in a double-blind cross-over trial involving 22 patients

(11 women and 11 men, aged 22-68 yr). The duration of symptoms ranged from 2-30 yr, averaging 7 yr. The trial included 2 treatment periods of 4 weeks each under either placebo or active drug. Three patients withdrew, 1 due to vertigo induced by the drug. Mild side effects, noted in 4 others who did complete the trial, included headaches, vertigo, nausea and increased irritability. During the first week of the trial, an almost identical response to placebo and active drug was noted. After 2 weeks, however, the active group alone continued to improve. After 4 weeks the difference in response was quite obvious. After the cross-over of the active drug with placebo, the improved state continued for a fortnight. However, after that time, the symptoms worsened, giving evidence that the placebo was ineffective compared with mepiprazole. This also demonstrates that the irritable bowel syndrome is a chronic condition which can be helped, but not cured, by treatment.

8605 MEGACOLON: SPECIAL DIAGNOSTIC AND THERAPEUTIC FEATURES.

(E.) Tobon, F.; Schuster, M. M. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *Johns Hopkins Med. J.* 135(2):91-105, 1974.

Two types of megacolon exist: 1) Hirschprung's disease, associated with an aganglionic colon segment, and 2) idiopathic megacolon in which nerve cells can be demonstrated histologically. These two entities were compared in a review of 100 cases of megacolon seen over a 10-yr period. Of these, 40 were Hirschprung's disease and 60 were idiopathic. Of the diagnostic tests used, manometry was the most accurate (100%). Histological appearance was more helpful in diagnosing idiopathic megacolon, whereas barium enema was more helpful with respect to Hirschprung's disease. The ratio of males to females was 2:1 with idiopathic and 9:1 with Hirschprung's megacolon. The familial incidence of Hirschprung's disease was 9.5% and, unlike previously reported, familial involvement occurred among males rather than females. In addition, the length of aganglionic colon did not tend to be similar in involved siblings. Mortality tended to be highest when there was familial involvement and did not depend on the length of the aganglionic segment. Down's syndrome occurred in 5.4% of the cases of Hirschprung's disease. Idiopathic megacolon showed no pattern of genetic predisposition. Clinically, patients with Hirschprung's disease experienced constipation during the 1st yr of life more frequently (96%) than did idiopathic megacolon patients (57%). Encopresis was present in 45% of the idiopathic megacolon patients but in none of the Hirschprung's patients. Personality disorders were present most frequently (63%) in patients with idiopathic megacolon plus encopresis, but generally were not seen in patients without encopresis or in patients with Hirschprung's disease. Sphincter tone tended to be normal or increased in patients with Hirschprung's disease but normal or decreased in idiopathic megacolon subjects. Stool could be detected clinically in the rectal ampulla of 94% of the patients with idiopathic disease but in only 50% of those with Hirschprung's disease.

8606 STERCORAL ULCERATION AND PERFORATION OF THE SCLERODERMATOUS COLON: REPORT OF TWO CASES AND REVIEW OF THE LITERATURE.

(E.) Robinson, J. C.; Teitelbaum, S. L. (Jewish Hosp. St. Louis, Mo.). *Dis. Colon Rectum* 17(5):622-632, 1974.

Two patients with scleroderma are reported whose deaths were due to colonic perforation associated with stercoral ulcers. The admitting diagnosis in a 54-yr-old woman presenting with abdominal pain and constipation was viral hepatitis and scleroderma. Two days after administration of a noneffective retention enema, the patient went into shock and became oliguric. At autopsy, the large intestine from cecum to mid-descending colon was markedly dilated and filled with feces. The transverse and proximal sigmoid colon were necrotic along the antimesenteric border; superficial ulcers were present throughout the left colon; and the sigmoid colon contained 2 perforations (1-2 cm in diameter) through which fecal matter was protruding. On histological examination, the epidermis was atrophic and the dermis collagenized. The ulcerated portions of the colon showed mucosal necrosis and marked atrophy of the true muscularis. The sigmoid colon at the site of perforation showed acute inflammation and necrosis of the wall. Mesenteric blood vessels near the perforation showed inflammatory changes, thrombosis, and destruction of the vessel wall. In a 70-yr-old woman, the admitting diagnosis was probable hernia with obstruction and scleroderma; her symptoms included abdominal pain, nausea, and vomiting. X-rays showed a severely impacted colon which was unresponsive to laxatives, enema, or stimulation. Pseudodiverticula were apparent on barium enema examination. Two weeks prior to death signs of sepsis appeared although blood cultures did not yield bacterial growth. At autopsy, fibrous lesions were present between the spleen and splenic flexure. This portion of the colon was markedly dilated and contained numerous stercoral ulcers up to 1 cm in diameter. The bowel wall was perforated at the point of splenic adhesions and impacted feces were present throughout the colon, particularly distal to the rend. Histologic findings included atrophic epidermitis, collagenized dermis, and severe atrophy of almost all the muscularis propria. The colon was ulcerated and inflamed in the vicinity of the perforation; the residual bowel wall underlying the ulcerated areas was infiltrated by bands of collagen. The frequency of colonic involvement in patients with scleroderma suggests a predisposition to colonic rupture. The importance of preventing constipation in these patients is stressed, as is the need of laparotomy to relieve prolonged obstipation.

8607 SPONTANEOUS SPIROCHETE INFESTATION IN THE COLONIC MUCOSA OF HEALTHY MEN.

(E.) Minio, F.; Tonietti, G.; Torsoli, A. (2nd Med. Clin., Univ. Rome, Italy). *Rend. Gastroenterol.* 5 (3):183-195, 1973.

Ultrastructural studies of the colonic mucosa from 10 apparently healthy male volunteers (aged 24-40 yr) revealed the presence of spirochetes in the colonic lumen and in contact with the superficial and cryptic cells in 4 biopsies (both ascending and descending large bowel portions) from 2 of the subjects. The spirochetes were found in the hairy coat (between the microvilli and within the epithelial cells), the intercellular spaces, and the lamina propria. The infested epithelial cells often showed non-specific alterations such as interruption of the apical plasma membrane, swelling of mitochondria, and degenerative changes of cytoplasmic areas. In the lamina propria, some of the spirochetes were free while others were phagocytosed by macrophages. Structures resembling spirochetes in shape and size were occasionally contained in the capillary walls. Microorganisms resembling *Escherichia coli* were also occasionally observed in contact with the surface epithelium, though not within the epithelial cells or the lamina propria. A scarcity of microorganisms within the cryptic lumens is possibly due to a local accumulation of mucus which might prevent spirochetes from entering into the crypts.

8608 PNEUMATOSIS CYSTOIDES INTESTINALIS TREATED BY OXYGEN BREATHING. *(E.)* Hoflin, F.; van der Linden, W. (Central Hosp., Ostersund, Sweden). *Scand. J. Gastroenterol.* 9(5):427-430, 1974.

The use of oxygen breathing therapy to successfully treat 2 cases of pneumatosis cystoides intestinalis, a disease characterized by gas-filled cysts in the wall of the intestine, is described. Both patients (a 52-yr-old woman and a 60-yr-old man) had a past history of pulmonary disorders, including bronchial asthma, a common feature of the condition. In both cases the cysts were confined to the colon. Gas analysis of the contents of the cysts showed them to contain a high percentage of hydrogen (up to 20%). Both patients were successfully treated with oxygen breathing therapy (68-72% oxygen) for 5 days. This treatment resulted in the complete disappearance of all roentgenographic and sigmoidoscopic evidence of the disease as well as improvement in the clinical condition of the patients. Neither patient has exhibited relapse thus far. Although the pathogenesis of the condition is not clear, the association with asthma seems to be a common feature of the disease; an allergy could possibly serve as their common basis.

8609 PROBLEMS IN THE DIAGNOSIS OF DIVERTICULITIS IN THE YOUNG. *(E.)* Kim, U.; Dreiling, D. A. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.). *Am. J. Gastroenterol.* 62(2):109-115, 1974.

The correct diagnosis of sigmoid diverticulitis in 5 men (aged 24-37 yr) was delayed because of their age and because the typical radiologic features of the disease were not seen in 3 of the 5 cases. In 1 patient presenting with perforated diverticulitis, barium enema after transverse loop colostomy with drainage of a pericolic abscess showed multiple diverticula in the sigmoid as well as descending colon. Elective sigmoid resection was based on a diagnosis of sigmoid diverticulitis made 5 yr earlier. Barium enema examination in the 2nd case showed multiple diverticulosis and diverticulitis with possible intramural abscess formation of the sigmoid colon. Sigmoid resection and end-to-end anastomosis with complementary diverting transverse colostomy was done. In the 3rd patient, preoperative emergency gastrografin enema showed a segment of the sigmoid colon in spasm. No other pathology was evident except for signs of extrinsic compression on the colon. Emergency laparotomy revealed sigmoid diverticulitis with a ruptured pericolic abscess, but after a loop transverse colostomy with drainage of the abscess cavity, barium enema showed a normal colon with the exception of an old walled-off perforation. A sigmoid resection was done. The 4th patient underwent a transverse colostomy and drainage after emergency laparotomy showed sigmoid diverticulitis with pericolic abscess. A postcolostomy enema showed extravasation of the dye from the sigmoid colon without other features of diverticular disease; repeat barium enema 1 month later revealed a persistant sinus tract. A perforated sigmoid diverticulum, walled-off by adjacent loops of small intestine, was found at laparotomy and treated by sigmoid resection. The 4th patient's history included 1 diverting transverse colostomy for acute sigmoid diverticulitis and another for a colovesical fistual. Laparotomy demonstrated a markedly thickened sigmoid colon with chronic inflammatory lesions and a fistulous tract between the lower sigmoid colon and posterior wall of the bladder. The patient underwent a high anterior resection with closure of the fistulous opening. These cases indicate that diverticular colonic disease in young patients requires a more aggressive surgical approach.

8610 DIVERTICULAR DISEASE. POSSIBLE CORRELATION BETWEEN LOW RESIDUE DIET AND RAISED INTRACOLONIC PRESSURES IN THE RABBIT MODEL. *(E.)* Hodgson, J. (Bronx VA Hosp., N.Y.). *Am. J. Gastroenterol.* 62 (2):116-123, 1974.

Rabbits fed a low-residue diet for 4 months as a model for diverticular disease developed a contracted colon with raised intraluminal pressures and temporary intertenial diverticula in response to neostigmine (0.05 mg/kg i.v.). Rabbits fed on a normal high-residue laboratory diet did not develop such changes. Rabbits on the standard diet had a mean fecal weight of 87.3 g/day while rabbits on the low-residue diet had a mean daily fecal weight of only 2.7 g. Transit time was 24 hr on the normal diet and 48 hr on the low-residue diet. It is suggested that in low-residue states, the intracolonic lumen has to be reduced to control a low fecal volume; without colonic narrowing and raised intracolonic pressure, diarrhea may occur. With a high-fecal residue, it would only be necessary for a wide diameter colon to exert minimal pressure for control to be achieved. In man, maintenance of the intracolonic lumen to control a low-residue fecal stream might lead to colonic muscle thickening, shortening, and diverticula formation.

8611 MOTILITY EFFECTS OF OPERATIONS PERFORMED FOR DIVERTICULAR DISEASE. *(E.)* Smith,

A. N.; Kirwan, W. O.; Shariff, S. (Dept. Clin. Surg., Univ. Edinburgh, Scotland). *Proc. R. Soc. Med.* 37 (10):1041-1043, 1974.

Control subjects and patients with uncomplicated diverticular disease of the colon were studied on their habitual diet before and after the addition of 20 g of unprocessed bran. A study was also made using patients who underwent either myotomy or resection of the pelvic colon for diverticular disease. There was no difference in basal motility between normals and patients before or after myotomy. Colonic activity had been significantly increased after all forms of stimulation in diverticular disease, with the greatest effect occurring after prostigmine. These responses were reduced to normal levels by myotomy. Resection of the sigmoid colon did not restore the inherent abnormality of the large bowel muscle to normal. Myotomy and resection patients were followed for 3 yr. A fall in the mean motility index occurred during the 1st yr following myotomy, but over the total period there was considerable return in the mean pressure activity. In contrast, the motility index after colon resection rose to levels very slightly above those recorded before operation. In comparing the effects of bran in normal subjects and patients, the transit time was significantly reduced in the latter. Stool weight was increased by an average of 63 g in normal subjects and 17 g in patients. Bran therapy did not alter the basal motility in patients, but the response to prostigmine fell by 50%. Thus there seems to be a marked diminution in response to motor stimuli in patients with diverticular disease who are fed bran. Intraluminal pressure in myotomy patients fed bran fell and remained low compared to patients treated by resection and bran. The continuing high pressure found in patients after resection suggests that these patients could repeat the cycle of events which originally promoted the development of the diverticula. The return of intraluminal pressure after myotomy is gradual, approximately 60% at 3 yr and almost complete at 5 yr. This rise can be counteracted by keeping the patient on bran prophylactically. The failure of resection to change intraluminal pressure can also be reversed by bran. Myotomy, which initially effectively lowers the intraluminal pressure, emphasizes the importance played by the circular muscle of the pelvic colon in diverticular disease.

8612 DIET AND DIVERTICULAR DISEASE. *(E.)* Parks, T. G. (Dept. Surg., Queen's Univ., Belfast, Northern Ireland). *Proc. R. Soc. Med.* 67(10):1037-1040, 1974.

Epidemiological studies confirm that diverticular disease is not racial in origin. Rather, such studies show that if a community eats a diet which is depleted of cereal fiber, diverticular disease will become relatively common within 30 yr. The prevalence of diverticular disease in Western civilizations may be related to the ingestion of a diet deficient in fiber and rich in carbohydrate. By adding indigestible fiber to the diets of diverticular patients, the frequency of defecation was only marginally increased in contrast to the considerable increase in the bulk of the stool. A high intake of indigestible fiber may lead to an increase in the stool weight of 100%, but simultaneously may only increase the frequency of defecation by 10-20%. When 70 patients received a high fiber/low sugar diet, including unprocessed bran, for an average of 22 months, symptoms were relieved or abolished in over 85% of the cases. This included relief from painful disease and accompanying symptoms such as abdominal distension and flatulence. In another 40 patients, abdominal discomfort, distension and flatulence were somewhat accentuated initially, due to forcing of the narrowed colon to deal with considerably increased bulk in the fecal stream. This discomfort phase seldom lasted more than 3-6 weeks. In a study measuring transit time, Ugandan villagers eating a bulky diet passed 80% of the markers in 35.7 hr compared with 76.1 hr in a group of English schoolboys on a refined diet. In a study measuring fecal weight, diverticular patients on a low residue diet had a fecal output of less than 100 g/day while those on a high residue diet with a bran supplement had a stool weight approaching 200 g daily. Under the latter conditions the colonic wall expends less effort in segmentating and propelling the less viscous fecal residue.

8613 LONGITUDINAL FISTULA OF THE COLON IN DIVERTICULITIS. *(E.)* Loeb, P. M.; Berk, R. N.; Saltzstein, S. L. (Sch. Med., Univ. California, San Diego). *Gastroenterology* 67(4):720-724, 1974.

A longitudinal intramural fistula of the colon appeared in a patient with diverticulitis. The patient, a 68 yr old man, was admitted with pain and vomiting of 2 weeks duration. Barium enema examination showed irregularity and thickening of the interhaustral folds in the sigmoid colon with numerous diverticula. The 11-cm long paracolic fistula filled with barium and communicated with the lumen at multiple points. A fiberoptic colonoscope showed normal mucosa except for the orifices of numerous diverticula in the sigmoid colon. In this patient there were no clinical, radiographic, or pathological features of granulomatous colitis. The terminal ileum, proximal colon, and perianal area were normal. The fistula was subserosal, with no transmural inflammation or granulomatous reaction. This case demonstrated that the presence of a longitudinal fistula greater than 10 cm cannot be considered pathognomonic of granulomatous colitis.

8614 FAECAL FLOW PATTERNS IN CHOLERRHEIC ENTEROPATHY AND COLONIC DIVERTICULAR DISEASE. *(E.)* Findlay, J. M.; Mitchell, W. D., Anderson, A. J. B.; Eastwood, M. A.; Smith, A. N. (Western Gen. Hosp., Edinburgh, Scotland). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 355-364.

Fecal flow patterns for 2 gastrointestinal extremes, cholerrheic diarrhea and diverticular disease, were examined by measuring the differential rates of recovery of equal doses of 2 synchronously fed markers. In the 1st experiment, patterns of fecal flow were investigated in 4 normal, healthy subjects passing normally formed stools, 5 hospitalized patients without diarrhea or diverticular disease who passed normal stools, and 5 patients with cholerrheic enteropathy. In the 2nd experiment 6 patients with diverticular disease were compared with 6 normals. Polyethylene glycol (500 mg) and chromium sesquioxide (500 mg), suitable markers for the liquid and solid phases of gut contents, resp., were fed synchronously 3 times/day for 4-11 days. The stools were pooled into 24-hr collections, and the markers were then estimated and expressed in terms of 24-hr outputs. There was no significant difference in the rate of throughput for the liquid and solid phase markers in healthy individuals and hospitalized patients with normal bowel habit, indicating that streaming does not usually occur. In cholerrheic enteropathy, the liquid phase marker was excreted 1.5 times faster than the solid phase, while in the diverticular disease group, the liquid phase was excreted 0.75 times slower than the solid phase marker. These findings may reflect the effects of colonic hypersegmentation on the relative distribution of the liquid and solid phases of gut contents.

8615 THE BIOLOGICAL SIGNIFICANCE OF RECTAL POLYPS. A COMPREHENSIVE STUDY OF 425 CASES.

(E.) Incze, F. (Stephen Hosp. of Metrop., Budapest, Hungary). *Am. J. Proctol.* 25(5):49-56, 1974.

Statistical findings from 425 cases of rectal polyps are presented in terms of morphological and histological characteristics, occurrence and recurrence rates, and survival rates of patients undergoing either radical or local surgery. The 425 cases were divided as follows: 333 patients with typical (benign) adenomatous polyps, 44 cases of adenomatous and villous polyps with atypia (4 recurrent), 35 cases of adenomatous and villous polyps with malignant tendency (1 recurrent), and 21 cases of carcinomatous polyps (3 recurrent). Males accounted for 62% of all cases of benign and malignant polyps and invasive cancers. The average age of the benign polypoid patient was 48.2 yr, that of the malignant polypoid patient 55 yr, and that of the cancerous patient 58.6 yr. Weight loss was experienced by every 7th benign, every 3rd malignant polypoid, and every 2nd invasive cancerous patient. Malignant and invasive cancerous patients had significantly shorter histories than benign patients. The characteristic location for benign polyps was anal, for the malignant (and related benign) polyps the pelvic part of the rectum, and for invasive cancer the ampullar part of the rectum. Malignant polyps were over 15 mm in size in 46% of cases, while 75% of the benign polyps were less than 15 mm in size. Over 80% of the malignant and all of the benign polyps were removed locally. Benign polypoid patients had a 6.9% recurrence rate for benign polyps and a 2.4% recurrence rate for malignant polyps. Malignant polypoid patients undergoing local surgery had a benign polyp recurrence rate of 12.5% and a malignant recurrence rate of 3.7%; those undergoing radical operations showed recurrences of 15% and 5% for benign and malignant polyps, resp. The operative mortality for radical removal of malignant polyps was 10%, while that for malignant patients undergoing local surgery was 4%. The overall mortality rate for local removal was 3.3% (death due to rectal cancer).

8616 ADENOMATOUS POLYPS OF LARGE INTESTINE IN AUTOPSY AND SURGICAL MATERIAL.

(E.) Sato, E. (Tohoko Univ. Sch. Med., Japan). *Gann* 65(4):295-306, 1974.

A survey of adenomatous polyps in autopsy and surgical specimens was conducted to assess their premalignant potential. Examination of the large intestine in 1,000 autopsy subjects yielded 95 patients (9.5%) with 127 adenomas. This frequency was significantly higher than that of hypertrophic mucosal protrusion (3.5%), juvenile-type polyp (0.3%), Peutz-Jeghers type polyp (0.2%), and hyperplasia (metaplasia) (1.1%). Adenoma increased in frequency with advancing age, appearing in 33.3% of octogenarians. The right colon (51.2%) was the most frequent adenomatous site, followed by the distal transverse and descending colon (23.6%). The adenomas were found in the sigmoid colon or rectum in 18% of subjects. Analysis of the age distribution of 116 surgical patients with 150 adenomas revealed that satellite polyps were most numerous between 60 and 69 yr of age, whereas adenomas in noncancerous bowel were most frequently observed in the 40's. Histological atypia was related to the size and location of adenomas. In the autopsy series atypia was most prominent in the lower large bowel. The incidence of focal malignancy in adenomas was 21.4% in females and 14.1% in males. Adenomas of the surgical series, obtained mostly from the lower tract, generally showed advanced atypia. Adenomas with focal malignancy were found in 13.3% of the surgical series but rose to 32.6% in adenomas of over 10 mm in diameter.

8617 THE SIGNIFICANCE OF PAPILLARY FEATURES IN POLYPS OF THE LARGE INTESTINE.

(E.) Kurzon, R. M.; Ortega, R.; Rywlin, A. M. (Mt. Sinai Med. Ctr., Miami Beach, Fla.). *Am. J. Clin. Pathol.* 62(4):447-454, 1974.

Histological studies were performed on 662 surgically removed polypoid epithelial lesions of the large intestine. The polypoid lesions were classified as adenomas, papillomas, mixed lesions (adenomatous and papillary features), or hyperplastic polyps. Carcinoma was found in 48% of the papillomas, 18% of the mixed lesions, and 1% of the adenomas. Among the hyperplastic polyps, 3 (5%) contained a mixture of hyperplastic and carcinomatous glands. Eighty percent of the carcinomas were superficial and 20% were invasive. Metastases occurred in 1/3 of the invasive carcinomas and in none of the superficial carcinomas. The presence of a papillary growth pattern in colonic polyps appears to be associated with an increased malignant potential.

8618 HISTOPATHOLOGICAL ANALYSIS OF BENIGN POLYPS IN PATIENTS WITH CARCINOMA OF THE COLON AND RECTUM.

(E.) Ekelund, G.; Lindstrom, C. (Malmo Gen. Hosp., Sweden). *Gut* 15(8):654-663, 1974.

All benign polyps in a 10-yr series of 960 patients with colorectal carcinoma from a defined population were analyzed to investigate the relationship between benign epithelial neoplasms and adenocarcinoma of the colon and rectum. All cases where histological specimens of the polyps were available were reclassified according to morphological type and grade of differentiation. Polyps were found in 215 patients (132 men and 83 women) with a median age of 65-69 yr. Of 381 polyps available for histological review, 308 were benign epithelial neoplasms, 46 metaplastic, and 27 miscellaneous types. Almost 1/4 of all benign epithelial neoplasms were adenovillous lesions. In men, 54% of the polyps were observed in the sigmoid colon and rectum; a 38% occurrence of polyps in these regions was seen in women. Benign epithelial neoplasms tended to be situated in the vicinity of coexisting carcinoma. The differentiation of benign epithelial neoplasms tended to be poorer with decreasing distance from the anus and with increasing size of the lesion. Metaplastic polyps (46) were found in 26 patients (15 men and 11 women); 23 of the polyps were seen in men and 23 in women. Thirty were found in cases with solitary carcinoma and 16 in cases with multiple carcinomas. None of the metaplastic polyps were found in patients under 50 yr of age. Metaplastic polyps found in the sigmoid colon or rectum accounted for 84% of those observed. Of 27 miscellaneous polyps observed, 20 were lesions with microscopically normal mucosa, 3 were inflammatory, and 4 were mesenchymal. The findings tend to support a relationship between benign epithelial neoplasms and colorectal carcinoma.

8619 THE EPIDEMOLOGIC PATHOLOGY OF CARCINOMAS OF THE LARGE BOWEL. *(E.)* Bert, J. W.; Godwin, II, J. D. (Natl. Cancer Inst., Bethesda, Md.). *J. Surg. Oncol.* 6(5):381-400, 1974.

From the Ends Results Group Registery, 60,1930 cases of histologically confirmed cancers of the large intestine were analyzed by histologic type. Adenocarcinomas were the standard against which cancers with other diagnoses were compared. Colloid carcinoma (4.6% of all cancers) made up 13% of cancers of patients under 30 yr, particularly men, and was twice as frequent in blacks as in whites. Colloid cancers of the right colon, including the appendix, had relatively high survival rates while those of the left colon, rectosigmoid, and rectum had survival rates below those for adenocarcinomas at the same sites. Papillary carcinomas had a better than average prognosis (56% 5-yr survival while polypoid carcinomas had the best prognosis of any carcinoma (77% 5-yr survival). Adenosquamous and squamous cell carcinomas in the rectum resembled anal cancers in the high frequency of women, the high frequency of blacks, and the greater proportions of patients under 40 yr. The one similarity between rectal epidermoid and colonic adenosquamous cancers was their equally poor prognosis: 34 and 25% 5-yr survival compared with 52% for anal epidermoid cancers. Malignant carcinoids in the appendix resembled benign carcinoids of that organ; 5-yr survival rates for rectal and colonic carcinoids were 67% and 48%, resp. Rectal carcinoids were usually common in blacks (33% of all patients with this tumor). Grade appeared to be an independent prognostic parameter, although low grade of malignancy implied an early stage; the lower the grade the more localized the cancer and the fewer distant metastases. Each of the special types of cancer of the intestine studied had sufficient differences in presentation and behavior to justify being distinguished from adenocarcinoma.

8620 CEA LEVELS AND PROGNOSIS IN COLON CARCINOMA. *(E.)* Bivins, B. A.; Boyd, C. R.; Meeker, Jr., W. R.; Griffen, Jr., W. O. (Med. Ctr., Univ. Kentucky, Lexington). *J. Surg. Oncol.* 6(5): 413-421, 1974.

The rate of fall of carcinoembryonic antigen (CEA) in the postoperative period was studied in 16 patients (14 men and 2 women, average age 57 yr) with colorectal carcinoma admitted for diagnosis and treatment. Clinical follow-up was conducted for an average of 9 months. Of the 16 patients, 14 (88%) had elevated preoperative levels of CEA. The mean value of elevation was 9.8 ng/ml. Dukes Class C lesions were present in 15 patients; 11 patients had potentially curative resection. In 6 patients, elevated preoperative CEA titers returned to normal between 1 week and 3 months postoperatively. One of these 6 patients returned after 20 months for a perineal recurrence of the adenocarcinoma. At the time of his readmission the CEA titer was normal, 2.2 ng/ml. In 3 patients, elevated preoperative CEA levels did not return to normal up to 6 months postoperatively, but the patients have remained clinically free of disease. Two patients with normal preoperative CEA levels showed rises in CEA levels quite promptly in the postoperative period. Both experienced a return of the CEA titer to normal over 2 to 3 months. Of the 5 patients who underwent only palliative procedures, all continued to have high CEA titers. The slow decline of CEA in this study compared to other investigations may result from suppression or destruction of the residual tumor by the host immune mechanism. All patients in this study had advanced lesions and residual tumor may indeed be a possibility. It is suggested that failure to detect an early decline in CEA levels to normal may not imply a poor prognosis.

8621 RELATIONSHIP OF CARCINOEMBRYONIC ANTIGEN TO BLOOD SUBSTANCES A AND i: EVIDENCE THAT THE ANTIGENIC SITES ARE ON DIFFERENT MOLECULES. *(E.)* Cooper, A. G.; Brown, M. C.; Kirch, M. E.; Rule, A. H. (Tufts Univ. Sch. Med., Boston, Mass.). *J. Immunol.* 113(4):1246-1251, 1974.

Extracts of 7 primary adenocarcinomas of the colon and 6 colonic carcinomas metastatic in the liver were obtained from human specimens during surgery and autopsy and assayed for the presence of blood group substance A and i activities with an automated quantitative hemagglutination-inhibition system. Carcinoembryonic antigen (CEA) activity was simultaneously assayed by the zirconyl phosphate gel radioimmunoassay. Isoelectric focusing of a perchloric acid tumor extract containing all 3 antigen activities indicated a similar dissociation constant value for the 3 antigens. However, A- or i-specific affinity gel adsorption experiments showed that only the corresponding blood group antigen activity was removed from tumor extracts. CEA activity remained essentially the same after adsorption by these gels. Significant blood group activity could not be demonstrated in preparations of highly purified CEA or in CEA from which *N*-acetylneuraminic acid and fucose had been removed. Conversely, CEA activity was absent from preparations of purified blood group antigens and could not be unmasked by removal of the immunodominant β-galactose of the i antigen with β-galactosidase. The antigenic sites for CEA and blood group A and i antigens appear to be located on different molecules in colonic carcinoma extracts. There was no correlation between CEA levels and blood group antigen levels in the extracts. The highest A antigen levels were present in primary colonic adenocarconomas, whereas the highest i antigen levels were found in metastatic colonic carconomas. This suggests that in those cells which metastasize, there is a selective diminution of those glycosyl transferases which are responsible for the addition of the terminal sugars conferring ABH blood group specificity onto a precursor i antigen.

8622 BLOOD GROUP SUBSTANCES (BG) AS CARCINOFETAL ANTIGENS IN CARCINOMAS OF THE DISTAL COLON. *(E.)* Denk, H.; Tappeiner, G.; Holzner, J. H. (Univ. Pathol. Anat. Inst., Vienna, Austria). *Eur. J. Cancer* 10(8):487-490, 1974.

The presence of blood group substances (BG) was studied using the mixed cell agglutination reaction in a group of 33 colonic carcinomas, including 2 carcinomas of the cecum (22 patients with BG-A and 11 patients with BG-B) and 8 metastases to the liver from colonic carcinomas. BG-A was positive in 15 of the 22 colonic carcinomas (68.2%) and BG-B was positive in 5 of 11 (45.5%). In most of the tumors, the entire tumor area was BG-positive. Even superficially localized carcinomas bordering the lumen of the gut were BG-positive while the surrounding non-neoplastic mucosa did not express BG-like activity. Normal non-neoplastic mucosa of the descending and the pelvic colon and rectum were invariably BG-negative, contrary to the mucosa of the cecum which contained BG in the goblet cells. Adenomatous polyps of the colon without histologic evidence of malignancy (5 cases) did not contain BG. Of the 8 liver metastases, 6 expressed BG activity in uniform distribution, 1 in patchy distribution and 1 was negative. Necrotic areas of positive carcinomas were BG-positive as well. Liver and Kupffer cells were BG-negative. Erythrocytes and endothelial cells showed positive mixed-cell agglutination reaction in accordance with the erythrocyte blood group of the patient. BG noncompatible with the blood group of the patient was not observed. The positive mixed-cell agglutination reaction was abolished by absorption of the BG antisera with their respective isologous erythrocytes. Since the mucosal cells of the whole colon contain BG in the fetal period which, however, rapidly disappear after birth, reappearance of BG in the tumor may represent derepression of embryonic gene functions during carcinogenesis. Therefore, normal antigens like BG act as "carcinofetal antigens" in certain carcinomas of the distal large bowel. The localization of BG in primary and secondary colonic carcinomas differs from CEA. Thus the immunologic cross reactivity between BG and CEA noted with purified substances is not demonstrable in tissue sections with the morphologic method used.

8623 IMMUNE REACTIVITY OF LYMPHOID TISSUES ADJACENT TO CARCINOMA OF THE ASCENDING COLON. *(E.)* Mavligit, G. M.; Jubert, A. V.; Gutterman, J. U.; McBride, C. M.; Hersh, E. M. (M. D. Anderson Hosp. Tumor Inst., Houston, Tex.). *Surg. Gynecol. Obstet.* 139(3):409-412, 1974.

The immunologic reactivity of lymphoid tissues neighboring carcinoma of the right colon was studied in 9 patients (aged 45-74 yr) with a lymphocyte blastogenic response method. All of the patients underwent right hemicolectomy for primary adenocarcinoma of the cecum or ascending colon. Mesenteric lymph nodes were obtained from 4 patients, appendix lymphocytes from 3 patients, and lymphocytes from the terminal part of the ileum and peripheral blood from all 9 patients. Positive blastogenic responses to phytohemagglutinin were observed in 22 of 25 lymphocyte preparations tested. The responses were of equal incidence and magnitude, except among lymphocytes derived from the terminal part of the ileum where both the incidence and magnitude of response were lower. Blastogenic responses in mixed leukocyte reaction varied. Peripheral blood lymphocytes and lymph node lymphocytes were highly reactive both in terms of positive incidence and magnitude, while appendix lymphocytes and lymphocytes from the terminal part of the ileum were less reactive or unreactive for 2 of 3 appendixes and 7 of 9 ileal preparations. Blastogenic responses to pokeweed mitogen were also equally distributed among different preparations, except for the lowered responses of lymphocytes from the terminal part of the ileum. Responses to streptolysin O were of a generally lower magnitude and less frequently positive than the responses to the mitogens. The responses were equally distributed, again except for the lower responses of lymphocytes from the terminal part of the ileum. Tumor-induced blastogenesis among autologous lymphocytes was detected in 3 of 5 lymphocyte preparations from the terminal part of the ileum. The responses of peripheral blood lymphocytes to autochthonous tumor were of the same magnitude and incidence, while appendix lymphocytes and lymph node lymphocytes remained totally unreactive to tumor cells. These different responses probably reflect different bone marrow-derived and thymus-dependent subpopulations among the tissues and in some instances, an immunosuppressive effect exerted by the tumor.

8624 DIFFUSE COLONIC MUCOSAL HYPERPLASIA. MORPHOLOGY AND SIGNIFICANCE. *(E.)* Prior, J. T.; Dunn, E. (Upstate Med. Ctr., Syracuse, N.Y.). *Arch. Surg.* 109(4):575-577, 1974.

A 43-yr-old man presented with adenocarcinoma of the rectum in which the surrounding mucosa was the site of several hyperplastic foci. This case suggests that mucosal hyperplasia is either not generally recognized or possibly ignored by both clinicians and pathologists. The hyperplastic foci showed a uniform structure; the contours were bosselated and mushroom-shaped with a generally smooth, free surface. The mouths of crypts of Lieberkuhn were wider than normal, and the individual cells tended to take a more intense hematoxylin reaction than the adjacent uninvolved mucosal epithelium. An overall increase in the number of columnar epithelial cells was noted at the expense of decreased goblet cell elements. The component cells were larger than normal, crowded together, and showed a tendency to stratification. Individual cell polarity was maintained. Mitotic activity was not increased. The stroma of the hyperplastic foci were compressed by the enlarged epithelial cells, but contained the usual number of round cells. Discrete lymphoid nodules with prominent germinal centers were located in the lamina propria and were associated with the majority of the lesions. Occasionally the hyperplastic foci were unassociated with lymphoid tissue and, conversely, several submucosal nodules were noted that had no relation to epithelial hyperplasia. Rarely, true polyps were noted of the adenomatous variety, although an occasional lesion contained isolated fronds consistent with the mixed or composite variety. In 1 of these tumors a diagnosis of carcinoma *in situ* could be made. The polyps were also invariably associated with mucosal lymphoid nodules. This case, showing both hyperplasia and polyps in the presence of a carcinoma, gave the opportunity to trace the sequential evolution of the benign lesions to carcinoma. This combination may be important in view of current immunological concepts linking host defenses to lymphocytic activity. While the hyperplasia-to-polyp sequence seems clear, multiple sections from the carcinoma and its contiguous areas failed to show evidence of a benign lesion.

8625 THE ASSOCIATION OF NEOPLASMS OF THE COLON AND RECTUM. WITH PRIMARY MALIGNANCIES OF OTHER SITES. *(E.)*

Schoenberg, B. S.; Christine, B. W. (Mayo Grad. Sch. Med., Rochester, Minn.). *Am. J. Proctol.* 25(4):44-60, 1974.

The association of colon and rectum neoplasms with primary neoplasms of other organ systems was analyzed by a retrospective analysis of the hospital records of 12,729 colon cancer patients, 8,083 rectal cancer patients, and 100,648 patients with malignancies at other sites. Overall, patients with colon cancer had a 1.44-fold higher risk of developing a secondary primary than the age and sex-matched controls. The excess risk of developing a 2nd nonsimultaneously diagnosed malignancy was greatest for colon, rectum, uterine corpus and ovary, showing a 2-way association. Rectal cancer patients, however, were not at an overall high risk for developing a 2nd independent malignancy except for a few specific instances: colon, ovary, and prostate. A 2-way association was present only between rectal cancer and cancer of the rectum and colon. Possible sources of bias resulting in skewed data include possible misdiagnosis of metastatic disease as a 2nd primary and the fact that the population with 1 primary tends to be followed more closely than the general population, thus resulting in a higher incidence of discovery of a 2nd primary.

8626 INTRA-ARTERIAL COMBINED CANCER CHEMOTHERAPY IN TECHNICALLY INOPERABLE CARCINOMA OF THE ANUS AND RECTUM. *(E.)*

Fischerman, K.; Briand, P.; Olsen, J.; Nielsen, O. V. (Rigshosp., Copenhagen, Denmark). *Acta Chir. Scand.* 140(5): 416-421, 1974.

Intra-arterial combined cancer chemotherapy with 5-fluorouracil and vincristine was administered to 5 patients (3 men and 2 women, 48-71 yr of age) with technically inoperable rectal and anal carcinomas. The patients were catheterized through the superior hemorrhoid artery with a Watkin's catheter and continually infused with 5-fluorouracil (15 mg/kg/day) and vincristine (1 mg/week) for 6-21 days, depending on catheter function. In 2 patients the 5-fluorouracil treatment was continued systemically. Rectoscopy was performed each week to estimate changes in tumor size, obtain biopsies for histologic and cytologic evaluation, and assay LDH and phosphofructokinase activity in 3 of the patients. Reductions in tumor size were observed in all patients during and after treatment. Cytologic changes after 3 weeks of treatment suggested less tumor vitality. Both LDH and phosphofructokinase activity declined during the late stage of treatment, though in 2 of the 3 patients assayed a rise in the activities of both enzymes was noted about 10 days after termination of the infusion. The toxic effect on bone marrow was modest: only 1 patient showed a drop in leukocyte count to below normal. Normal mucosa was not affected by the cytostatic agents used; *in vivo* experiments with 7 pigs and 3 dogs subjected to extracorporeal gastric perfusions containing the cytostatic agent daunomycin confirmed the absence of effect on normal mucosa. The tumors in 2 of the patients were converted to operable ones, and the surgical removal of the rectum in each case was performed. Two patients died just after the intra-arterial treatment, 1 patient from pneumonia and the other from pulmonary embolism. Another patient lived 14 months after treatment and died from carcinoma. One of the surgical patients is still alive and well 30 months after rectum removal. Absence of a toxic effect on bone marrow or of damage to normal tissue, and reduction in tumor size, recommend intra-arterial treatment as increasing chances for survival in cases of inoperable rectal or anal carcinoma.

8627 THE PROPHYLACTIC USE OF ANTIBIOTICS IN SURGERY FOR COLONIC CARCINOMA. *(E.)*

Farmer, R. G. (Cleveland Clin. Fdn., Ohio). *Dis. Colon Rectum* 17(5):633-637, 1974.

A prospective clinical study was made of 39 patients undergoing surgery for newly diagnosed colonic carcinoma in the 1st half of 1973. All received mechanical cleansing consisting of a 48-hr preparation with castor oil, p.o., in the morning, followed by enema 4 times/day on each of 2 preoperative days. About 19 hr before the scheduled surgical procedure, 3 doses of neomycin and erythromycin base, 1 g each/dose, were given p.o. Enemas were given the morning of surgery and in the operating room just prior to surgery. Of the 39 patients, 28 (20 men and 8 women, average age 68 yr) received the total preoperative treatment while the other 11 received either single antibiotics or none. The locations of the carcinoma in these 28 patients were: sigmoid colon, 13; rectum, 2; descending colon, 2; transverse colon, 3; ascending colon, 4; and cecum, 4. Of these lesions 23 were resectable using the no-touch isolation technique. Of the 11 patients receiving other types of preoperative management (6 men and 5 women, average age 61 yr) 8 lesions were in the sigmoid, 2 in the cecum and 1 in the transverse colon of which 7 were resectable. No postoperative infections occurred in the 28 patients receiving preoperative antibiotic coverage plus mechanical cleansing. All had uneventful postoperative courses and short hospital stays. Of the 11 treated by other means, 2 had significant postoperative infections. This outcome confirms the efficacy of the combination of neomycin and erythromycin base in association with mechanical cleansing for preoperative preparation. The ease of administration, the short-term duration of the preparation, the lack of resistant organisms developing in this short period, and the realization that prophylactic antibiotics are only complementary to mechanical cleansing, adequate surgical technique, and postoperative care have led to a decrease in morbidity and mortality from postoperative sepsis.

LARGE INTESTINE

Ulcerative Colitis

8687 HYPOSPLENISM IN ULCERATIVE COLITIS. *(E.)* Ryan, F. P.; Smart, R. C.; Preston, F. E.; Holdsworth, C. D. (Roy. Infirm., Sheffield, England). *Lancet* (7876):318-320, 1974.

Blood films of 3 male patients with ulcerative colitis (ages 28, 65, and 52 yr at time of colitis development) were examined after a finding of Howell-Jolly bodies suggestive of hyposplenism in the blood film of 1 of the patients. Studies of the clearance of ^{51}Cr-labeled heat-damaged red blood cells revealed half clearance time values of 130 ± 6, > 171, and 92.5 ± 6 min, resp., for the colitis patients as compared to a normal range of 9.0-17.5 min (10 controls). Each patient thus displayed severe splenic hypofunction; no uptake was measurable over the spleen in any patient, confirming that the spleen was not clearing the damaged red blood cells from the circulation. Hyposplenism probably developed over the course of the colitis since retrospective examination of the patients' records revealed normal blood films when they first presented with colitis.

8688 HL-A 27 AND ARTHROPATHIES ASSOCIATED WITH ULCERATIVE COLITIS AND PSORIASIS. *(E.)* Brewerton, D. A.; Caffrey, M.; Nicholls, A.; Walters, D.; James, D. C. O. (Westminster Hosp., London, England). *Lancet* (7864):956-957, 1974.

The histocompatibility antigen HL-A 27 was identified with a 2-stage lymphocytotoxicity micromethod in only 22 of 300 controls as compared to 13 of 18 patients with ankylosing spondylitis and ulcerative colitis. The antigen was also identified in 10 of 41 patients with psoriasis and peripheral arthropathy, 4 of 9 patients with sacro-iliitis, and 9 of 10 patients with sacro-iliitis and spondylitis. Patients with ulcerative colitis and no arthropathy did not differ significantly from controls with respect to presence of the antigen. The histocompatibility antigen findings suggest that genetic factors are more important than previously thought in the complex overlapping relationships between inflammatory bowel disease, psoriasis, ankylosing spondylitis, peripheral arthropathy, Reiter's disease, and acute anterior uveitis. Approximately 6% of patients with ulcerative colitis have clinical ankylosing spondylitis, which is 30 times more frequent than in the rest of the population.

PANCREAS

8704 ANGIOGRAPHY IN PANCREATIC TRAUMA. *(E.)* Haertel, M.; Fuchs, W. A. (Univ. Hosp., Bern, Switzerland). *Br. J. Radiol.* 47(562):641-645, 1974.

The angiographic pattern of pancreatic trauma is described in reference to angiographic investigation of 125 patients with blunt abdominal trauma which revealed 4 cases with traumatic pancreatic lesions (3 females and 1 male, aged 4 to 52 yr). Of these 4, 2 had lacerations of more than 1 abdominal organ. Clinical features of traumatic lesions of the pancreas are not specific and are easily confused with other lesions. Elevation of the pancreatic enzymes, amylase and lipase, in the blood serum or peritoneal fluid strongly, but not specifically, indicate pancreatic lesions. Radiodiagnostic signs are unspecific and unreliable. Hemoperitoneum and/or local paralysis of the small intestine may be present. Only hematomas situated in the lesser peritoneal sac lead to rather characteristic ventral displacement of the stomach. Angiographic features include occlusion of pancreatic arteries and local impairment of the arterial circulation. Collateral circulation may develop. Additional displacement of adjacent arteries indicates hematoma. Displacement of the duodenum, stomach, proximal jejunum, and its supplying arteries, may occur. Arteriovenous shunting and extravasation of contrast material was not noted in these patients. The venous phase of the celiac and mesenteric angiogram are important diagnostic tools. The formation of a hematoma and post-traumatic edematous swelling of the pancreas compresses and obstructs the splenic vein situated on the dorsocranial aspect of the pancreas. Prestenotic dilatation of the splenic and portal vein and a collateral portal circulation may indicate portal venous obstruction. Pancreatic pseudocysts may develop within weeks as post-traumatic sequelae and may be noted angiographically by marked displacement of the otherwise normal arteries. Subphrenic abscess formation, also a complication of pancreatic trauma, may be diagnosed by angiography on the basis of arterial vascular displacement. Post-traumatic pancreatitis is indistinguishable from inflammatory pancreatic disease of other origin. Smooth circumscribed arterial stenosis, medial displacement of the gastroduodenal and pancreaticoduodenal arteries due to organ scarring, and postthrombotic changes of the splenic vein, are suggestive angiographic signs.

8705 ARGININE ESTERASE IN CYSTIC FIBROSIS OF THE PANCREAS. *(E.)* Rao, G. J. S.; Nadler, H. L. (Children's Mem. Hosp., Chicago, Ill.). *Pediatr. Res.* 8(6):684-686, 1974.

Arginine esterase activity in chloroform-ellagic acid-treated plasma from 11 patients with cystic fibrosis of the pancreas and 12 age-matched controls was resolved into its component fractions by ion-exchange chromatography on DEAE-Sephadex and electrofocusing on polyacrylamide gels. The activity was resolved into a fraction inhibited by soybean trypsin inhibitor and into a fraction resistant to soybean trypsin inhibitor. In plasma from cystic fibrosis patients, the fraction of activity inhibited by soybean trypsin inhibitor was approximately 30% of the corresponding fraction in control plasma. In contrast, the fraction of activity resistant to inhibition did not show any significant quantitative differences between control and patient plasma samples. Electrofocusing on 5% polyacrylamide gels at pH 5.0-8.0 and subsequent staining for arginine esterase activity showed qualitative changes between plasma samples from controls and cystic fibrosis patients. Six bands of arginine esterase activity were detected in control plasma samples. The most intense of the 6 bands were 3 bands (C, D, and E) clustered at the center of the gel. Plasma samples from patients contained only 5 bands. In 8 samples, band D was missing; in 2, band E; and in 1, band C. The data are consistent with and extend previous reports of differences in arginine esterase activity in plasma samples from patients with and without cystic fibrosis. The absence of a single band of arginine esterase activity is consistent with the absence of a specific arginine esterase isoenzyme in patients with cystic fibrosis.

8706 LIPASE-SECRETING ACINAR CELL CARCINOMA OF THE PANCREAS WITH POLYARTHROPATHY. A LIGHT AND ELECTRON MICROSCOPIC, HISTOCHEMICAL, AND BIOCHEMICAL STUDY. *(E.)* Burns, W. A.; Matthews, M. J.; Hamosh, M.; Weide, G. V.; Blum, R.; Johnson, F. B. (VA Hosp., Washington, D.C.). *Cancer* 33(4):1002-1009, 1974.

A functional acinar cell carcinoma of the pancreas is reported in a 52-yr-old chronic alcoholic whose most persistent complaint was of polyarthropathy, especially of the lower extremities. A malignant tumor of acinar cell origin metastatic to the liver was diagnosed pre-mortem by electron microscopy and confirmed at autopsy. The tumor contained abundant zymogen granules, and by histochemical and biochemical examination was seen to contain abundant lipase activity. It was proposed that electron microscopy should be used routinely in the diagnosis of exocrine as well as endocrine tumors of the pancreas, regardless of whether the specimen is obtained at surgery or autopsy.

PANCREAS

Pancreatitis

8714 PANCREATITIS AND LIPASE. A REEVALUATION WITH A FIVE-MINUTE TURBIDIMETRIC LIPASE DETERMINATION. *(E.)* Lifton, L. J.; Slickers, K. A.; Pragay, D. A.; Katz, L. A. (E. J. Meyer Mem. Hosp., Buffalo, N.Y.). *JAMA* 229(1):47-50, 1974.

Lipase activity was simultaneously determined with amylase activity in the sera of 30 patients hospitalized with acute pancreatitis. Amylase activity was assayed with an amyloclastic procedure and lipase activity with a turbidimetric procedure. On admission, 70% of the patients had increased serum amylase, 63% had increased lipase, and 83% had either increased lipase or amylase, or both. All patients had an increase in the level of at least 1 enzyme during the course of their illness. In 9 patients the lipase activity remained elevated with a normal amylase level, whereas in 6 the amylase level remained elevated after the lipase level had returned to normal. In 21 patients peak amylase and lipase values were within 2 days of each other, and in 7 cases the lipase peaked later than the amylase. Neither amylase nor lipase elevation was related to any specific clinical criterion:

nausea and vomiting, abdominal pain, and history of alcoholism were each present in more than 75%, while 40% had a history of pancreatitis. The results do not confirm the traditional thesis that lipase elevation occurs later and lasts longer than that of amylase. The measurement of amylase and lipase together will improve diagnostic accuracy in acute pancreatitis.

8715 PLASMA GASTRIN RESPONSES TO ARGININE IN CHRONIC PANCREATITIS. *(E.)* Kalk, W. J.; Vinik, A. I.; Bank, S.; Hayes, J. R.; Ardill, J.; Buchanan, K. D.; Keller, P.; Jackson, W. P. U. (Univ. Cape Town, Med. Sch., South Africa). *Diabetes* 23(4):264-267, 1974.

Serum gastrin responses to i.v. L-arginine hydrochloride (30 g in 150 ml saline infused over 30 min) were measured in 18 insulinopenic and noninsulinopenic patients with chronic pancreatitis (12 men and 6 women, aged 21-65 yr) and in 7 healthy men (aged 26-37 yr). The 2 patient groups did not differ significantly from controls with respect to mean fasting gastrin levels, total gastrin increment in response to arginine, or maximal gastrin increment. Pancreatitis did not impair gastrin responses to arginine nor was gastrin an important determinant of insulin secretion in these patients.

8716 IDIOPATHIC ACUTE PANCREATITIS IN CHILDREN. ASSOCIATION WITH A CLINICAL PICTURE RESEMBLING REYE SYNDROME. *(E.)* Morens, D. M.; Hammar, S. L.; Heicher, D. A. (Kauikeolani Children's Hosp., Honolulu, Hawaii). *Am. J. Dis. Child.* 128(3):401-404, 1974.

Idiopathic acute pancreatitis, which was clinically indistinguishable from Reye's syndrome occurred in 2 girls, aged 6 yr. Both children were entirely well 2 days before hospital admission when they developed the nonspecific symptoms of cough, coryza, sore throat, earache, and emesis. Both progressed to a comatose state characterized by severe hepatic dysfunction. Evidence of severe pancreatitis was also found at laparotomy in one and at autopsy in the other patient, who died on the 5th day of illness. However, the original diagnosis of Reye's syndrome could well be questioned in each case, for in case 1 fatty infiltration of only the liver was present, and in patient 2, no fatty changes in the viscera were found. It is not likely that the encephalopathy resulted from circulating pancreatic enzymes, as the patient who recovered had no neurological damage and the patient who died showed no evidence of brain digestion at autopsy. It is suggested that these examples of acute pancreatitis may represent one basic disease process whose more common form of presentation is that originally described by Reye, or conversely, that more than one disease process may give rise to similar clinical findings. It is felt that in the investigation of patients with a clinical picture suggesting Reye's syndrome, tests of pancreatic function should be included.

8717 PULMONARY HYPERTENSION IN ACUTE HEMORRHAGIC PANCREATITIS. *(E.)* Halmagyi, D. F. J.; Karis, J. H.; Stenning, F. G.; Varga, D. (Dept. Surg., Univ. Sydney, Australia). *Proc. Int. Symp. Gastrointest. Motility, 4th, 1973* pp. 637-642.

Acute hemorrhagic pancreatitis was induced in 8 greyhounds by effective surgical excision of the portion of duodenum just distal to the pylorus and including the major pancreatic duct, by ligation of the common bile duct and subsequent heparinization. The results were compared to changes in 5 sham-operated greyhounds. Pulmonary and femoral blood flows, systemic and pulmonary arterial blood pressures, blood gases, plasma levels of lactate, catecholamines, amylase, and glucose were measured prior to and for 24 hours following the interventions. Induction of pancreatitis was followed by gradual hypotension and 6 of 8 dogs were dead after 24 hr; all sham-operated dogs remained alive the next day. Neither hypovolemia nor activation of vasodilator agents could be identified as the cause of circulatory failure. In the pancreatitis group mean pulmonary arterial pressure was 26 ± 5 and in the sham-operated group 15 ± 4 mm Hg; pulmonary "wedge" pressure was 6 ± 5 mm Hg, cardiac index 2.2 ± 0.3 liters/min, and arterial blood gases were normal in both groups. In 3 human patients admitted for acute hemorragic pancreatitis, Swan-Ganz catheters were inserted and pulmonary arterial mean pressures were found to be 36, 22, and 32 mm Hg, resp., with normal (8-10 mm Hg) pulmonary "wedge" pressure and normal cardiac outputs. The similarity of these experimental findings with clinical results suggests that pulmonary hypertension is a hitherto unrecognized consequence of acute pancreatitis and that it is likely to be related to pulmonary arteriolar constriction secondary to the release of some vasoactive material from the injured pancreas.

8718 NASOGASTRIC SUCTION IN THE TREATMENT OF ALCOHOLIC PANCREATITIS. *(E.)* Levant, J. A.; Secrist, D. M.; Resin, H.; Sturdevant, R. A. L.; Guth, P. H. (Wadsworth VA Hosp. Ctr., Los Angeles, Calif.). *JAMA* 229(1):51-52, 1974.

Of 29 patients with mild to moderately severe acute alcoholic pancreatitis, 15 were randomly allocated to treatment with nasogastric suction and 14 to no-suction therapy. The mean age of the patients in the suction and no-suction groups was 41.6 and 44.4 yr, resp. Antibiotics, anticholinergics, and antacids were not used. There were no significant differences between the 2 groups in duration of the following: abdominal pain, abdominal tenderness, nausea, narcotic requirement, fever, and elevated serum and urine amylase levels. Although a larger proportion of patients treated with suction became pain-free within 2 days, the difference disappeared by the 3rd day. Treatment without suction was associated with earlier return of normal bowel sounds and smaller risk of prolonged hyperamylasemia (2 of 14 patients compared with 7 of 15 in the suction group). Because nasogastric suction provided no clear-cut advantages in this group, it might be considered elective rather than mandatory in the treatment of mild to moderately severe acute alcoholic pancreatitis.

LIVER AND BILIARY TRACT

8742 IDENTIFICATION OF α-ANTITRYPSIN IN LIVER CELLS OF PATIENTS WITH α_1-ANTITRYPSIN DEFICIENCY: ULTRASTRUCTURAL AND IMMUNOCYTOCHEMICAL STUDY. *(E.)* Feldmann, G.; Bignon, J.; Chahinian, P.; Guesnon, J.; Gilet, M. (INSERM, Beaujon Hosp., Clichy, France). *Digestion* 10(3):219-220, 1974.

Ultrastructural and immunocytochemical studies were conducted on liver specimens from 5 severely emphysematous adults with α_1-antitrypsin deficiency, 4 of whom were homozygous ZZ and 1, heterozygous FZ. Immunocytochemical techniques, using anti-α_1-antitrypsin antibodies labeled with horseradish peroxidase, demonstrated the presence of α_1-antitrypsin in liver cells. Deposits were seen in the lumens, membranes, and in ribosomes of the rough endoplasmic reticulum of hepatocytes. These findings suggest that in patients with α_1-antitrypsin deficiency, the protein is synthesized by the ribosomes but is not completely transported to the plasma, thus accumulating in the lumina of the rough endoplasmic reticulum.

8743 SYMPTOMS OF PRIMARY CANCER OF THE LIVER. *(Rus.)* Shain, A. A. (Tiumen Med. Inst., USSR). *Vopr. Onkol.* 20(9):50-56, 1974.

Clinicopathology of primary hepatic cancer was studied in 385 patients of whom 190 had opisthorchiasis. The main clinical symptoms included the pain sensation in the right subcostal region (95.3% of patients with opisthorchiasis, otherwise 96.1%); weakness, emaciation, loss of appetite (80.5, 70.4, 68.8% resp.); tumorous hepatomegaly syndrome (94.8 ± 1.1%) the size of the liver in 95 patients averaging 17.5 cm upon hospitalization; fever (69.9 ± 2.4%); ascites (44.7 ± 2.5%), and jaundice (35.1 ± 2.4%). There was a greater incidence of accumulation of serous fluid in the abdominal cavity in patients with cirrhosis-associated cancer (71.2 ± 5.9% against 45.5 ± 3.0% in noncirrhotic cancer). Autopsies of 220 patients with hepatic cancer showed jaundice in 84 (38.2%) caused in 50 cases (60%) by metastases in the periportal lymphatic nodules constricting the bile ducts. Tumorous hepatomegaly involved substantial enlargement of the liver, painful palpation, hardening and tuberosity of the surface tissues. No essential symptomatic differences were observed between opisthorchiasis primary cancer and cancer not associated with parasitic invasion. Splenomegaly was atypical of hepatic cancer and opisthorchiasis (4.9% of cases). Drug-resistant fever in opisthorchiasis is indicative of possible hepatic cancer.

8744 FATAL LIVER DISEASE OF UNKNOWN ORIGIN IN TWO ADOLESCENT BROTHERS. *(E.)* Theodor, E.; Ravid, M.; Jaffe, R.; Cohen, B. E. (Chaim Sheba Med. Ctr., Tel-Hashomer, Israel). *Am. J. Dis. Child.* 128(5):727-730, 1974.

Two brothers had repeated episodes of vomiting, hepatomegaly, and laboratory evidence of deranged liver function. Despite complete clinical recovery between attacks, the patients died in hapatic coma at the ages of 14 and 16 yr, resp., the younger 8 yr and the older 1 1/2 yr after onset of illness. Results of a liver biopsy performed on the older brother during an asymptomatic interval was normal. Autopsy, performed only on the younger brother, revealed a mild liver fibrosis linking the portal tracts and creating a lobular effect. The lobule showed pronounced fatty change that was most prominent at the periphery of the lobule. The droplets were microvesicular. Sudanophilic droplets were found in the proximal tubules of the kidney, especially in the renal medulla, and in the lungs. There was no evidence for chronic active hepatitis, recurrent or protracted hepatitis, hereditary fructose intolerance, or repeated exposure to toxins. Reye's syndrome was considered in view of the histological changes in the younger brother, but recurrent episodes of the syndrome in the same patient have not been reported. Additionally, neither brother showed hypoglycemia. Although fatal hemorrhage in a 3rd brother during circumcision may have been a manifestation of familial neonatal liver disease, the existence of a hereditary disorder was not confirmed.

8745 PRIMARY CAUSE OF DECREASED FUNCTIONAL RESERVE IN THE LIVER OF ICTERIC PATIENTS AND RATS. *(E.)* Ozawa, K.; Yamada, T.; Ida, T.; Yamaoka, Y.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Surg. Gynecol. Obstet.* 139(3):358-362, 1974.

Biochemical studies of mitochondrial metabolism were conducted on hepatic tissue from adult male Wistar rats made icteric by ligation of the common bile duct and on hepatic biopsy specimens from 13 icteric patients. Phosphorylase activity/U of cytochrome a(+a_3), as determined by the change in pH resulting from conversion of ADP to ATP, fell to about 50% of control values following either common bile duct ligation or ligation of a branch of the portal vein. Partial hepatectomy, however, resulted in a 200% stimulation (compared with controls) in phosphorylase activity of hepatocyte mitochondria from rats subjected to bile duct ligation 3 weeks previously. This stimulation was felt to be due to enhanced portal blood supply to regenerating tissues. Hepatocyte mitochondrial phosphorylase activity/U of cytochrome a(+a_3) from icteric patients with low cytochrome a(+a_3) levels was considerably greater than that of nonicteric controls, while that from icteric patients with high cytochrome a(+a_3) levels was decreased. These findings in rats and icteric patients are explained on the basis of previous reports showing the presence in portal blood of a factor, possibly insulin, which stimulates liver mitochondrial oxidative phosphorylation. It is suggested that in rats the reduced phosphorylase activity in icteric liver is due to a decrease in the inherent sensitivity of the mitochondrial respiratory enzymes to this factor. The increase in phosphorylase activity in icteric patients with low cytochrome a(+a_3) may be a compensatory event produced by increased levels of portal blood stimulating factor.

8746 NON-PARASITIC LIVER ABSCESS.

(E.) Schraibman; I. G. (Infirm., Rochdale, England). *Br. J. Surg.* 61(9):709-712, 1974.

The clinical features of 15 cases of nonparasitic hepatic abscess verified at surgery or autopsy were studied. All patients were febrile at one time during the illness. Approximately 50% complained of abdominal pain. Nausea and vomiting occurred in a few and weight loss was significant only if there was a delay in diagnosis. Only 4 patients were jaundiced and in 3 the liver was easily palpable. White blood cell count was elevated (> 10,000) in 10 of 13 patients studied, and erythrocyte sedimentation rate was raised (> 20 mm/hr) in all 9 cases where it was measured. Elevated serum bilirubin and alkaline phosphatase were useful, but not diagnostic, studies; serum enzymes, however, were of no diagnostic value. Of particular interest was the fact that all 11 patients studied showed a reversal of the serum albumin:globulin ratio (< 1) and in only 1 case was serum albumin > 3 g%. Also of significant diagnostic value was the liver scan which showed a filling defect in 4 of 4 patients in which it was done. A lesion into the abdominal cavity was found in 9 patients and could have been the source of infection resulting in hepatic abscess. In none of the 7 patients who died, was the diagnosis of hepatic abscess suspected before death. Treatment was by drainage in 10 patients, 8 of whom recovered. No patients with multiple small abscesses survived.

8747 PATHOLOGY AND PATHOGENESIS OF LIVER DISEASE IN ALPHA-1-ANTITRYPSIN DEFICIENT INDIVIDUALS.

(E.) Aagenaes, O.; Fagerhol, M.; Elgjo, K.; Munthe, E.; Hovig, T. (Rikshosp., Oslo, Norway). *Postgrad. Med. J.* 50(584):365-375, 1974.

Of 6 pediatric patients hospitalized with liver disease, biliary atresia was suspected in 3 and umbilical bleeding was present in 2. Laboratory studies showed an increase in transaminase, alkaline phosphatase, serum bilirubin and bile acids; there was also some increase in serum lipids and steatorrhea. The diagnosis in all cases was intrahepatic cholestasis. Past history disclosed low average birth weights of 3,000 g. Previously reported infants with known α_1-antitrypsin deficiency who did not develop neonatal liver disease had normal birth weights. Thus, the low birth weights in the present study could be explained by developing liver disease in the fetus. After the cholestasis subsided, the liver continued to be enlarged and firm, having the picture of a slowly progressing cirrhosis. It is suspected that 10-20% of the children with α_1-antitrypsin deficiency have liver disease. It is suggested that cirrhosis develops in these individuals through a metabolic or nutritional mechanism: the liver becomes damaged because its cells cannot secrete an abnormal protein synthesized from a mutation at the locus for the α_1-antitrypsin structural genes.

8748 BIOCHEMICAL ABNORMALITIES IN REYE'S SYNDROME.

(E.) Alvira, M.; Forman, D. T. (Evanston Hosp., Ill.). *Anal. Clin. Lab. Sci.* 4(6): 477-483, 1974.

Sera from 9 children (aged 7 months to 8 yr) with Reye's syndrome confirmed at autopsy were examined prior to death. Four patients presented with serum hypoglycemia and decreased glucose concentration in cerebrospinal fluid. Serum potassium was elevated in all cases, urea nitrogen in 7, and creatinine, uric acid, and ammonia in 5. Arterial blood gas analyses showed a negative base excess in 9 patients and a decreased pH in 5. Hypocapnia was present in 8 cases and mild hypoxemia in 40%. All patients tested had a marked increase of serum aspartate and alanine aminotransferase, lactic dehydrogenase, and creatine phosphokinase. Biochemically, these changes may be explained by a sudden insult to the intracellular respiration causing an increased tissue metabolism resulting in an elevated endogenous nitrogen load. The consistent elevation of creatine phosphokinase implies a severe impairment of oxidative metabolism. Studies of creatine phosphokinase isoenzymes in 2 children showed marked elevations in sketetal muscle and minor increases in heart. While this may be due to the observed primary hypoxemia and hypocapnia, the severe mitochondrial injury seen in 3 patients suggests a mitochondrial origin of creatine phosphokinase in these patients. Serum gamma-glutamyl transpeptidase activity and bilirubin concentrations were not increased in this group, indicating that liver damage in Reye's syndrome is not as important a factor as has been reported. Preliminary findings of an ongoing study indicate a progressive rise in creatine phosphokinase is associated with a grave prognosis.

8749 FIVE-YEAR FOLLOW-UP STUDY OF PATIENTS WITH NONALCOHOLIC AND NONDIABETIC FATTY LIVER.

(E.) Massarrat, S.; Jordan, G.; Sahrhage, G.; Korb, G.; Bode, J. C.; Dolle, W. (Med. Polyclin., Phillips Univ., Marburg/Lahn, Germany). *Acta Hepatogastroenterol.* 21(3):176-186, 1974.

Ninety-two patients with histologically verified fatty liver but without diabetes mellitus or a history of excessive alcohol consumption underwent follow-up examination 40.8 (± 7.3) months after initial presentation (first observation period). A 2nd liver biopsy was performed on 56 of these patients. In addition to the clinical examination, the following data were obtained: degree of overweight, transaminase activities, alkaline phosphatase, BSP retention after 45 min, serum electrophoresis, bilirubin, cholesterol, blood sugar, and glucose assimilation coefficient. Fat accumulation in the liver was assessed histologically. Liver and spleen scans were made of the 65 patients who were examined as outpatients 2 yr later (second observation period). In spite of the continuing heavy deposition of fat in the liver of some patients, clinical, chemical (during both observation periods), or histological data (first period) showed no transition to liver cirrhosis. At the last examination, 7 patients had fasting blood sugar levels of more than 100 mg%, but only 1 had to be treated dietetically for diabetes mellitus.

8750 MARKED FATTY LIVER ASSOCIATED WITH HYPOTHALAMIC LESIONS - TWO AUTOPSY CASES. *(E.)*

Miyasaki, K.; Miyachi, Y.; Ooiso, Y. (Kobe Univ. Sch. Med., Japan). *Acta Pathol. Jap.* 24(3):405-412, 1974.

Fatty liver was noted as a common finding in a 24-yr-old housewife with diabetes insipidus and autopsy findings of superior pharyngeal carcinoma with metastasis to the base of the skull, from the right inner ear to pituitary, sella turcica, and hypothalamus, and to the liver, and in a 45-yr-old housewife with marked hyperorexia, obesity, and autopsy findings of encephalomalacia of the hypothalamus. No clinical records on special food habits were available. In both cases, amenorrhea, endometrial atrophy of the uterus and no Graafian follicles in ovaries were found. It is suggested that changes of some releasing hormones in the hypothalamus may influence the metabolism of neutral fat. It may be possible to postulate a center for the regulation of neutral fat metabolism in the hypothalamus.

8751 AN AUTOPSY CASE OF CONGENITAL HEPATIC CELL TUMOR.

(E.) Okayasu, I.; Mori, W.; Hatanaka, M. (Tokyo Med. Dental Univ., Japan). *Acta Pathol. Jap.* 24(3):387-392, 1974.

A congenital hepatic cell tumor was found in a female newborn autopsied 4 hr after birth. The infant was born of a 37-yr-old woman who had no contributing history except for having taken a diuretic at the terminal stage of the pregnancy for late pregnancy toxicosis. The tumor was small hen-egg sized, whitish grey in color, rather soft in consistency, and located at the middle part of the right lobe of the liver. The tumor cells resembled fetal hepatic cells, showing a regular, cord-like arrangement probably of 2-cell thickness. The most conventional diagnosis for this tumor would be hepatoblastoma. However, neither sarcomatous spindle cells nor bone and cartilage tissue, which are often seen in hepatoblastoma, were found in this tumor. It is concluded that the tumor described occupies a specific position among hepatic tumors because it is congenital, has no distinctive capsule, has a close resemblance histologically to fetal hepatic cells, and has a higher degree of extramedullary hematopoiesis than adjacent normal liver tissue.

Hyperbilirubinemic States

8757 CONJUGATED HYPERBILIRUBINEMIA IN EARLY INFANCY. A REASSESSMENT OF LIVER BIOPSY.

(E.) Brough, A. J.; Bernstein, J. (Wayne State Univ. Sch. Med., Detroit, Mich.). *Human Pathol.* 5(5):507-516, 1974.

Liver biopsy was performed in 158 cases to differentiate biliary obstruction from hepatocellular disease in the evaluation of conjugated hyperbilirubinemia in newborns and young infants. There were 195 biopsy specimens, of which 98 were percutaneous needle and 97 were open wedge biopsies. In this series there were 10 misdiagnoses (6.3%) which could have been reduced to 4.4%. Diagnostic error resulted from the misinterpretation of ductal abnormalities: from the "over-reading" of bile duct proliferation in 9 children shown subsequently to recover from their jaundice; and from the "under-reading" in 1 child shown subsequently to have biliary tract obstruction. Under-reading is infrequent, while over-reading is a major cause of histopathologic error. Marked bile duct proliferation may also obscure the histologic appearance of α_1-antitrypsin deficiency. To accurately evaluate hepatocellular disease, the histopathologist should be alert not only to the absence of an inflammatory cell response suggesting the possibility of metabolic disease, but also to a deficiency of intrahepatic bile ducts which may be an indication of abnormalities in bile salt metabolism. The major difficulty in this series was caused by the occasional occurrence of bile duct proliferation in hepatitis; its presence is therefore not specific for biliary tract obstruction. It is suggested that bile duct proliferation in hepatitis results from transient or segmental cholangiolar injury with resultant, perhaps temporary, obstruction.

8758 CONGENITAL DYSERYTHROPOIETIC ANEMIA AND THE DUBIN-JOHNSON SYNDROME.

(E.) Clauvel, J. P.; Erlinger, S. (St. Louis Hosp., Paris, France) *Gastroenterology* 67(4):686-690, 1974.

The clinical and laboratory features of a patient suffering from the Dubin-Johnson syndrome and type II congenital dyserythropoietic anemia are described. Deep jaundice was noticed at birth. At age 26 yr, he was admitted for additional investigation of the jaundice which had persisted with varying intensity. Electron microscopy revealed a double cell membrane, probably originating from the endoplasmic reticulum, in the periphery of most of the late erythroblasts. At phase contrast microscopy of the ghost, pieces of this membrane remained in 43% of the mature red cells. Serological studies showed the red cells were strongly agglutinated by anti-i and anti-I sera. Red cell survival was slightly shortened. Iron incorporation into erythrocytes was decreased and surface counting showed predominant bone marrow uptake. Serum total bilirubin was 44 mg/100 ml; SGPT, 110 Karmen U; alkaline phosphatase, 11 KA U. Histological examination of a needle biopsy specimen showed normal liver architecture and the presence, chiefly periportal, of abundant dark brown pigment in hepatocytes. There was slight portal fibrosis, mild steatosis, and iron in periportal liver cells, all resulting from iron overload. The hematological findings correspond well with type II congenital dyserythropoietic anemia. A secondary rise in plasma bromsulphalein concentration was noted after a single injection, characteristic of the Dubin-Johnson syndrome. Likewise the brown pigment observed at optical microscopy in parenchymal liver cells was also characteristic of the Dubin-Johnson syndrome. The association of an increased bilirubin production (chiefly due to ineffective erythropoiesis) and an impaired biliary excretion of bilirubin (as a result of the Dubin-Johnson syndrome), probably accounted for the very high bilirubin level.

8759 THE USE OF PHOTOTHERAPY IN NEONATAL JAUNDICE.

(E.) Rusu, O.; Stambler, S.; Milcoveanu, E.; Taulescu, G.; Kehaian, M.; Herscovici, P.; Sufrin, W. (Polizu Clin. Hosp., Bucharest, Rumania). *Rom. Med. Rev.* 18(1):56-61, 1974.

A follow-up study was performed on 450 neonates treated for jaundice by phototherapy. Jaundice was separated into the following categories: hyperbilirubinemic jaundice without isoimmunization; jaundice due to ABO incompatibility; and jaundice due to Rh incompatibility. Premature infants with hyperbilirubinemic jaundice were exposed 3 days after birth. Infants with isoimmunization-caused jaundice were exposed during the first 3 days of life. In 38.46% of the cases, barbiturates were combined with phototherapy. The duration of treatment averaged 3.1 days. Phototherapy was effective in treating neonatal hyperbilirubinemic jaundice by accelerating the process of bile pigment clearance and preventing hyperbilirubinemia from reaching the danger threshold. Serum bilirubin values fell during treatment by 61-69%. In jaundice due to isoimmunization, phototherapy served only as an adjuvant method, major clearance being obtained by exsanguinotransfusion. However, in cases of severe isoimmunization, phototherapy lowered the number of repeated exsanguinotransfusions by almost 50%. The incidence of nuclear jaundice at necropsy in 2 periods of the same length, before and after phototherapy, showed a significant decrease in the incidence of this pathologic condition. The treatment itself was well tolerated by children. Transient hyperthermia with agitation occurred in 13 cases (3%), digestive disturbances in 37 cases (8.2%), and skin color changes in 10 cases (2%). Premature interruption of phototherapy caused a strong hyperbilirubinemia rebound in 29 cases (8%). In the course of phototherapy, serum bilirubin values must be determined at regular intervals of 8-12 hr. Attenuation of the jaundice does not reflect actual values of circulating bilirubin. Critical levels may be reached although masked by fading of the jaundice following exposure to light.

8760 PHOTOTHERAPY OF NEONATAL HYPERBILIRUBINEMIA: BILIRUBIN IN UNEXPOSED AREAS OF THE SKIN.

(E.) Vogl, T. P. (Magee-Woman's Hosp., Pittsburgh, Pa.). *J. Pediatr.* 85(5):707-710, 1974.

The effect of shading small areas of the skin with opaque patches during continuous phototherapy was studied in 35 infants. Two patches, 4 cm square, were applied to each infant, one over the sternal area and one on the center of the back. While the serum bilirubin concentration was rising, the range of equivalent serum bilirubin concentrations between patched and unpatched areas was 0.0-8.5 mg/100 ml, average 3.5 mg/100 ml. During periods of declining serum bilirubin concentrations, the values of equivalent serum bilirubin concentration for patched and exposed areas were 1-11 mg/100 ml, average 5.7 mg/100 ml. Analysis of the color differences between patched and exposed skin areas, for the periods of rising and falling serum bilirubin concentration for each infant, ranged from -6.5 to 8.9 mg/100 ml, average 2.2 mg/100 ml. No correlation was found between the color difference observed and any of the following factors: sex, cause of jaundice, direct and indirect Coombs tests, duration of phototherapy, breast *versus* bottle fed, gestational age, and history of asphyxia. After termination of phototherapy, the color differences between patched and unpatched areas faded slowly over a period of at least 3 hr. The fact that any color difference at all in the skin can be maintained over an area as small as 4 cm square indicates that the bilirubin is rather firmly bound in the tissue and relatively uninfluenced by serum bilirubin concentrations. This represents a potent defense mechanism of the body against bilirubin encephalopathy, since the bilirubin is liberated from serum albumin when it migrates into the tissue and the albumin is then free to bind additional bilirubin released from the reticuloendothelial system, while the bilirubin in the skin is not easily available to re-enter the bloodstream. The idea that bilirubin leaves the vascular space more easily than it reenters it is supported by the finding that the color difference is greater during times of decreasing than in times of increasing serum bilirubin concentration, when the tissue appears to more readily absorb bilirubin from the vascular space. This study supports the theory that the principal site of action of phototherapy is in the skin. From the width of the color transition region at the edge of the patch (1 or 2 mm) in the presence of an extended light source, the maximum depth of action of the light was determined to be less than 2 mm by a construction from geometric optics.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

8761 ACUTE HEPATOTOXICITY OF TANNIC ACID ADDED TO BARIUM ENEMAS. *(E.)* Eshchar, J.; Friedman, G. (Asaf Harofe Government Hosp., Zerifin, Israel). *Am. J. Dig. Dis.* 19(9):825-829, 1974.

The possible harmful effects of 1% tannic acid in 1,500 ml of barium sulfate used for barium enemas were evaluated. Liver function tests were performed before and after x-ray examination in 2 groups of unselected patients: 50 patients (26 women and 24 men, aged 10-78 yr) without prior evidence of liver damage (group A), and 11 subjects (7 women and 4 men, aged 20-72 yr) with liver damage (group B). In group A mild rises in transaminases appeared in 3 patients: 1 with apparent coronary ischemia; and the 2nd due to prolonged retention of the contrast material for more than half an hour. The 3rd patient was a boy, aged 11 yr, and was the only patient to experience a rise in both SGOT and SGPT. Of the 11 patients in group B, 4 showed deterioration of liver function tests, particularly in BSP retention (3 cases) and alkaline phosphatase (1). Thus, barium enemas containing 1% tannic acid do not cause liver damage in adults, provided the colonic lesion is neither extensive nor severe, and there is no evidence of preceding liver damage. Caution must be exercised when administering tannic acid to persons with impaired liver function. Tannic acid should not be used where retarded evacuation of the bowel is to be clinically expected. The effect of tannic acid in adults with disturbed liver function and in children requires further evaluation.

8762 HEPATITIS FOLLOWING ACTINOMYCIN D AND IRRADIATION. *(E.)* Harris, F.; Cullity, G.; Lister, J. (Children's Hosp., Sheffield, England). *Proc. R. Soc. Med.* 67(8):756-757, 1974.

A boy (aged 2 yr and 9 months) was hospitalized with hematuria and a right loin mass. A nephroblastoma was removed by nephroureterectomy and actinomycin D (180 μg, 15 μg/kg) was given immediately and for 3 subsequent days. Radiotherapy was begun 10 days after operation and continued for 3 weeks. A total dose of 3250 rads was given to the right hemiabdomen from hemidiaphragm to sacral promontory. After 2 months time a right renal bed abscess required drainage and he was admitted with acute generalized edema and ascites. Liver function tests showed bilirubin 1.7 mg/100 ml, SGOT 360 and SGPT 200 milliunits/ml. Despite albumin infusions and diuretics, liver functions deteriorated further and the ascites required drainage. Thrombocytopenia persisted. Two weeks after laparotomy, radiographs showed elevation of the left hemidiaphragm. Liver function gradually improved and 12 weeks after biopsy only minimal uptake in the right hepatic lobe was noted on liver scan with markedly increased left lobe uptake. After 18 months, the platelet count rose to normal and the liver function also normalized. Such cases of severe radiation hepatitis in children are rare. There is evidence from animal studies that pretreatment with actinomycin D sensitizes the skin and gut to radiotherapy and increases the morbidity when radiation is directed to these tissues. When using the combined techniques of surgery, radiotherapy and chemotherapy, the timing of each individual procedure in relation to the others may be far more critical than previously supposed. This is particularly important in treating children where a permanent loss of growth in specific tissues can have exceedingly serious effects as the rest of the child matures.

8763 HEPATIC TOXICITY OF NITROSOUREA ANALOGUES. *(E.)* Lokich, J. J.; Drum, D. E.; Kaplan, W. (Children's Cancer Res. Fdn., Boston, Mass.). *Clin. Pharmacol. Ther.* 16(2):363-367, 1974.

A 70-yr-old man with carcinoma of the colon and a 66-yr-old man with carcinoma of the pancreas developed a mild hyperbilirubinemia with little alteration of serum enzymatic activity in association with combined streptozotocin and 1,3-bis(2-chloromethyl)-1-nitrosourea therapy. Hepatic scintigraphy revealed severe, reversible depression of radiocolloid uptake by hepatic phagocytes, suggesting that normal phagocytic function is sensitive to some toxic effects of these drugs. The pathological finding of hepatocyte necrosis was typical for subacute hepatitis and persisted in spite of clinical recovery. Recovery of phagocyte function may precede hepatocyte reconstitution, thus accounting for the disparate clinical and pathologic effects.

8764 TOXIC AND ALLERGIC LESIONS OF HEPATOBILIARY TRACT IN WORKERS HANDLING EPOXIDE COMPOUNDS. *(Rus.)* Parpalei, I. A. (Kiev Med. Inst., USSR). *Vrach. Delo* (8):134-137, 1974.

Clinical investigation of 110 persons handling epoxide compounds and 25 controls revealed hepatic changes involving enlargement of the liver, pain syndrome and dyspeptic discomfort in 49% of the cases and 4% of the controls. Hypergammaglobulinemia (23.6 ± 0.6%) was found in 58% of cases. Liver scanning and ^{198}Au-labeled hepatography revealed reticuloendothelial and vascular involvement. The isotope accumulation period reached 21 ± 2.5 min (compared with the normal of 10 min). Disorders of the hepatic blood supply tended to be more pronounced in the workers with a longer record of handling epoxide compounds. Positive intracutaneous tests with albumin and epoxide resin allergen were found in 83% of cases and none in controls. Antibody titration against albumin-epoxide complex ranged from 1:64-1:254; antihepatic antibodies, 1:64-1:508. Liver biopsy revealed various degrees of hepatitis in all workers handling epoxide compounds. The changes in the hepatobiliary system are classified as having toxic and allergic origin.

8765 HALOTHANE HEPATITIS — A REPORT OF FIVE CASES. *(E.)* Paull, A.; Hall, P.; Grant, A. K. (Queen Elizabeth Hosp., Adelaide, South Australia). *Aust. NZ J. Med.* 4(3):304, 1974.

8766 THE FUNCTION OF THE LIVER IN WORKERS HANDLING CHLORPROMAZINE AND SOME OTHER SUBSTANCES. *(Rus.)* Liubchenko, D. N.; Drozdova, G. A.; Borodulina, O. V.; Boiarchuk, Z. I.; Turaev, R. N.; Dubova, V. G. (M. F. Vladimirsky Region. Clin. Inst., Moscow, USSR). *Gig. Tr. Prof. Zabol.* (9):47-48, 1974.

8767 ULTRASTRUCTURAL CHANGES IN THE LIVER OF METHOTREXATE-TREATED PATIENTS WITH PSORIASIS. *(E.)* Horvath, E.; Kovacs, K.; Ross, R. C. (St. Michael's Hosp., Toronto, Canada). *Eur. J. Clin. Invest.* 4(5):319, 1974.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

8768 DIFFERENCES BETWEEN AUSTRALIA ANTIGEN POSITIVE (VIRUS B) AND AUSTRALIA ANTIGEN NEGATIVE (VIRUS A) HEPATITIS. *(E.)* Sama, S. K.; Tewari, S. G. (All-India Inst. Med. Sci., New Delhi). *Indian J. Med. Res.* 62(5):749-755, 1974.

Fifty-six adult patients with a diagnosis of viral hepatitis were studied. Patients with serum positive for hepatitis associated antigen (HBAg) or antibody to HBAg were taken as cases of virus 'B' hepatitis, while those having serum negative for both HBAg and antibodies to HBAg were considered as suffering from virus 'A' hepatitis. HBAg and antibody to HBAg in the serum were studied by agar gel diffusion, counter electrophoresis and solid phase sandwich radioimmunoassay. Twenty-six cases were determined to be virus A and 30 to be virus B hepatitis. The clinical picture and natural history of the 2 types of hepatitis are compared. Virus A hepatitis is short incubation or infectious hepatitis, and virus B hepatitis is long incubation or serum hepatitis. The majority of virus B hepatitis cases have an insidious onset. Anorexia, nausea, vomiting and fever are less frequent in virus B hepatitis and a fair number of patients have jaundice as the first manifestation. Cholestasis is more frequent in virus B hepatitis. Fulminant course with fatal outcome and chronic course are predominantly the features of virus B hepatitis. Virus A hepatitis is relatively benign with quick recovery in most of the cases.

8769 PITFALLS IN THE STUDY OF HEPATITIS A. *(E.)* Almeida, J. D.; Gay,. F. W.; Wreghitt, T. G. (Wellcome Res. Lab., Beckenham, England). *Lancet* (7883):748-750, 1974.

Fecal and serum samples from 12 cases of infectious hepatitis were examined by immune electron microscopy and double diffusion in agar gel. Electron microscope results were not interpretable for fecal extracts treated with acute sera, but extracts reacted with convalescent sera contained distinctive aggregates with the appearance of immune complexes. No one type of structure predominated in these aggregates. All 12 fecal samples produced precipitin lines against some of the sera tested, with 7 extracts giving lines only to recovery serum. Of the 11 paired sera reacted with fecal extracts producing strong lines only against convalescent serum, 6 showed seroconversion to 1 or more antigens in the extracts. Seroconversion was also observed in some control fecal extracts. A reaction of identify was obtained between an antigen detected in the feces of infectious hepatitis cases, the feces of a patient with obstructive jaundice due to carcinoma of the pancreas, and pooled human globulin. The results illustrate the multiplicity and nonspecificity of the immune reaction in hepatitis.

8770 PLEURAL EFFUSION, RASH, AND ANERGY IN ICTERIC HEPATITIS. *(E.)* Owen, R. L.; Shapiro, H. (Sch. Med. Univ. California, San Francisco). *N. Engl. J. Med.* 291(18):963, 1974.

A 42-yr-old patient had a clinical course characteristic of self-limited type A viral hepatitis but presented with pleuritic pain, pleural effusion, and transient hematuria. During his acute illness the patient developed a papulovesicular skin rash and transitory cutaneous anergy, a rarely reported feature of viral hepatitis. The rash may have been complement mediated; serum complement (C3) was subnormal when it appeared. The effusion and anergy may have been part of a serum-sickness-like prodrome of viral hepatitis. Two prospective studies have indicated that effusion may be more usual in hepatitis than is commonly recognized. Early recognition of effusion may enable clinicians to determine whether tissue damage is indeed mediated by complement.

8771 LONG-INCUBATION POST-TRANSFUSION HEPATITIS WITHOUT SEROLOGICAL EVIDENCE OF EXPOSURE TO HEPATITIS-B VIRUS. *(E.)* Prince, A. M.; Brotman, B.; Grady, G. F.; Kuhns, W. J.; Hazzi, C.; Levine, R. W.; Millian, S. J. (New York Blood Ctr., N.Y.). *Lancet* (7875):241-245, 1974.

An agent other than hepatitis B (HB) virus seemed to be the cause of 36 (71%) of 51 cases of post-transfusion hepatitis identified during prospective biweekly serological follow-up of 204 cardiovascular patients. The sera of the 36 cases showed no evidence of the antigen or antibody response expected to accompany infection by HB virus and to be detectable by the sensitive assays used. Incubation periods and clinical and epidemiologic features were not consistent with hepatitis A. Cytomegalovirus-associated seroconversion was no more common among the HB-negative cases than among HB-positive cases or among patients who did not develop hepatitis. The data suggest that a large proportion of long-incubation posttransfusion hepatitis is unrelated to hepatitis B and that control of posttransfusion hepatitis will require identification of a hepatitis virus(es) type C.

8772 ASSESSMENT OF THE SENSITIVITY AND SPECIFICITY OF THE AUSRIA-125 KIT FOR DETECTION OF HEPATITIS-B ANTIGEN. *(E.)* Gera, K. L.; McKeering, L.; Halliday, J. W.; Powell, L. W. (Roy. Brisbane Hosp., Australia). *Aust. NZ J. Med.* 4(3):305, 1974.

The Ausria-125 radioimmunoassay kit for rapid detection of hepatitis B antigen (HBAg) was compared with the solid-phase radioimmunoassay (SPIRA) method. Of 331 sera, the SPIRA method detected 8 (2.4%) specifically positive for HB Ag compared with 9 (2.7%) detected by the Ausria-125 kit. Detection rates for counter-electrophoresis and agar gel diffusion were 0.9% and 0.06%, resp. The results indicate that the Ausria kit is probably as sensitive as other radioimmunoassay methods. However, doubtful results should be checked by the SPIRA or hemoagglutination techniques.

8773 TRANSPLACENTAL TRANSMISSION OF HEPATITIS-B VIRUS BY SYMPTOM-FREE CHRONIC CARRIER MOTHERS. *(E.)* Papaevangelou, G.; Hoofnagle, J.; Kremastinou, J. (Univ. Athens Med. Sch., Greece). *Lancet* (7883):746-748, 1974.

Transplacental transmission of hepatitis-B surface antigen (HB_sAg) and of hepatitis B virus was studied in 12 symptom-free chronic HB_sAg carrier mothers and their 15 babies. HB_sAg was present in the sera of the mothers throughout the study (at delivery and 3 and 6 months later). HB_sAg was detected in the cord blood of 3 of the 15 children, but subsequently was not detected except in 1 child who first became HB_sAg-positive at age 6 months. Antibody to HB_sAg was not demonstrated in the mothers or in their children during the first 6 months of life. Antibody to the core antigen (anti-HB_c) was always present in carrier mothers and in cord blood, but it disappeared from the sera of the newborns shortly after birth. These data indicate that children of chronic HB_sAg mothers generally do not become infected with hepatitis B virus before or at birth despite the known intense exposure to HB_sAg from the mother. Whether anti-HB_c is responsible for avoidance of infection is not known.

8774 FAMILIAL CLUSTERING OF HEPATITIS B ANTIGEN: A STUDY IN RELATIVES OF PATIENTS WITH LIVER DISEASE AND HEPATITIS B ANTIGENAEMIA. *(E.)* Bruguera, M.; Bosch, J.; Rodes, J.; Pedreira, J. (Clin. Prov. Hosp., Barcelona, Spain). *Br. Med. J.* 5929(3):495-497, 1974.

Of 100 family contacts of 29 patients with transient and persistent hepatitis B antigenemia, 12 were positive for hepatitis B antigen (HBAg). No relation was found between familial clustering and the nature of liver disease or the duration of antigenemia in the index cases. Eight of the affected relatives were apparently healthy HBAg carriers, 1 had cirrhosis, and 3 (in the same family) developed acute viral hepatitis. Sera from all positive members of 4 families (10 cases) were subtyped by agar gel difusion. Members of 2 families had subtype *ad* and those of the other 2 families had subtype *ay*. This finding together with the absence of parenteral exposure in the HBAg-positive family contacts suggests a nonparenteral spread of HBAg in families of patients with HBAg-associated liver diseases.

8775 TRANSMISSIBLE DISEASE AND BLOOD TRANSFUSION. *(E.)* Dodd, R. Y. (Blood Res. Lab., American Natl. Red Cross, Bethesda, Md.). *Science* 186(4169):1138-1139, 1974.

Recent studies indicate that the Dane particle is the infectious virion of hepatitis B. The specific nucleotide polymerase in the inner core of the Dane particle can be precipitated from serum specimens by prior treatment with serum containing antibodies to hepatitis B surface antigen (HB$_s$Ag). Antibody to the core is found in almost all HB$_s$Ag carriers and in certain HB$_s$Ag-negative donors implicated in cases of posttransfusion infectious hepatitis B. Other diseases with potential relevance to blood transfusion are Epstein-Barr virus and cytomegalovirus. Both are widely distributed in the normal population, and serologic or clinical evidence of exposure is frequently found in transplant or transfusion recipients. An association has been demonstrated between the number of transfused leukocytes and cytomegalovirus infection in the recipient. Other viruses potentially transmissible by transfusions are arboviruses and slow viruses. Parasitic diseases must be considered when potential blood donors have a history of residence in tropical areas.

8776 RECIPIENT'S HEPATITIS, AN INEVITABLE SIDE-EFFECT OF BLOOD TRANSFUSION. *(E.)* Fiedler, H. (German Red Cross Blood Transfusion Service, Munster). *Vox Sang.* 26(4):368-371, 1974.

In 37 cases of posttransfusion hepatitis, the recipient's blood was hepatitis-associated antigen (HAA)-positive in 13 cases, negative in 10 cases, and not tested in 14 cases. In the 13 cases of confirmed posttransfusion hepatitis type B, at least 1 HAA-positive donor was found by radioimmunoassay in 3 cases (23.1%) and 2 by electron microscopy in 5 cases (40.0%). No donor blood was HAA-positive on counterelectrophoresis. Overall rates of posttransfusion hepatitis were considerably higher in operated than in nonoperated patients. The results suggest that an unknown percentage of so-called posttransfusion hepatitis cases is due to extrahematogenic infections. In these cases the manifestation of the disease is apparently due to the patient's temporarily enhanced susceptibility rather than to the relatively small virus dose.

8777 ASYMPTOMATIC HEPATIC DISEASE IN BLOOD DONORS WITH HEPATITIS B ANTIGENEMIA. *(E.)* Vittal, S. B. V.; Dourdourekas, D.; Shobassy, N.; Gerber, M.; Telischi, M.; Szanto, P. B.; Steigmann, F.; Clowdus, B. F. (Cook County Hosp., Chicago, Ill.). *Am. J. Clin. Pathol.* 62(5):649-654, 1974.

Thirty asymptomatic blood donors were found to be positive for hepatitis-B antigen (HBAg) in a routine screening operation with counterimmunoelectrophoresis and solid-phase radioimmunoassay. All donors were 16-55 yr-old males, 4 of whom were volunteers and 26 paid donors. The donors had no history suggestive of hepatitis and no antibody to HBAg. Three were heroin addicts and 6 had histories of considerable alcoholic intake. All 30 donors had demonstrable biochemical and histologic abnormalities of the liver but remained asymptomatic throughout the period of HB antigenemia, which ranged from 13-72 weeks. Leukocyte migration inhibition was normal in 16 subjects and only slightly depressed in 4, indicating that depression of the cell-mediated immune response is not the cause of this clinical state. Regular long-term biochemical and histologic assessment of these individuals is planned to determine the natural course of this condition.

8778 DISTRIBUTION PATTERNS OF HEPATITIS B ANTIGEN IN THE LIVER. IMMUNOFLUORESCENCE STUDIES. *(E.)* Akeyama, T.; Kamada, T.; Koyama, M.; Abe, H. (Osaka Univ. Med. Sch., Japan). *Arch. Pathol.* 98(4):252-256, 1974.

The localization and distribution patterns of hepatitis B antigen (HBAg) in the liver of patients with various liver diseases were examined by a direct immunofluorescent antibody technique. A specific fluorescence was observed in 21 of 23 HBAg seropositive cases, in none of 14 HBAg seronegative cases, and in 4 HBAb seropositive cases. The fluorescence was mainly in the cytoplasma of liver cells. Four distribution patterns of fluorescence-positive cells were observed: solitary, focal, disseminated, and lobular. The HBAg distribution patterns changed from solitary to lobular as liver disease progressed to more chronic and severe forms. No asymptomatic carriers or patients with acute hepatitis and chronic persistent hepatitis showed lobular distribution, whereas almost all patients with chronic aggressive hepatitis, liver cirrhosis, and primary hepatoma with cirrhosis had disseminated and lobular patterns. These facts suggest that HBAg plays an important role in the progress of liver disease.

8779 HEPATITIS B ANTIGEN AND PATHOLOGICAL CHANGES IN THE LIVER. *(E.)* Vesely, V.; Soustek, Z.; Kulich, V. (Univ. Hosp. Dept. Blood Transfusion, Plzen, Czechoslovakia). *J. Hyg. Epidemiol. Microbiol. Immunol.* 18(2):234-239, 1974.

Hepatitis B antigen (HBAg) was demonstrated with double immunodiffusion and immunoelectrophoresis in the sera of 6 out of 110 autopsies (36 females and 74 males, dying of various diseases at the age of 3 weeks to 85 yr). The 6 subjects positive for HBAg consisted of 3 men (ages 81, 36, and 50 yr) and 3 women (ages 85, 64, and 48 yr). Histological examinations of the liver were made for all cases. Each positive finding for HBAg was associated with pathological changes in the liver. Liver changes which could be related to healed hepatitis were found in 20.90% of the cases, though serological findings were negative for these. Negative morphological and serological findings were recorded in 73.65% of the autopsies. Moderate diffuse liver fibrosis with proliferation of the connective tissue in the periportal fields was found in 17 of the 104 negative cases. Postnecrotic cirrhosis of the liver without icterus was observed in 1 case. Three cases were icteric, and 2 cases showed cardiac liver cirrhosis. Examination for HBAg was negative in 1 case of cytomegalic hepatitis and in 1 case of hepatitis in a female who was operated on for cholelithiasis and necrosis of the head of the pancreas 1 month prior to death. It is suggested that a positive finding of HBAg indicates acute or suffered viral hepatitis; a negative finding does not exclude this and is of no importance in assessing the state of liver function or in determining the extent of liver damage.

8780 MANGANESE, COPPER, AND ZINC CONCENTRATIONS IN SERUM AND PACKED BLOOD CELLS DURING ACUTE HEPATITIS, CHRONIC HEPATITIS, AND POSTHEPATITIC CIRRHOSIS. *(E.)* Versieck, J.; Barbier, F.; Speecke, A.; Hoste, J. (Academic Hosp., Ghent, Belgium). *Clin. Chem.* 20(9):1141-1145, 1974.

Manganese, copper, and zinc concentrations in the sera and packed blood cells of 46 normal controls, patients with acute (20 cases) and chronic (persistent or agressive) hepatitis (8), and 5 cases of postnecrotic cirrhosis were determined with neutron-activition analysis. Increased serum manganese concentrations (2.32 ± 0.96 ng/ml mean) were always observed during the active phase of acute icteric viral hepatitis (10 patients); slight increases in mean serum copper (1.43 ± 0.36 μg/ml) were also observed. Serum manganese normalized during the subsiding phase, and serum zinc was normal in all 10 subsiding cases. Serum copper was increased to 2.32 μg/ml in 1 case of hepatitis B antigen positive hepatitis. All 3 metals remained at normal values in the 4 cases of chronic persistent hepatitis. Mean serum manganese (0.84 ± 0.24 ng/ml) was significantly higher than normal in chronic aggressive hepatitis (4 cases), while mean serum zinc (0.79 ± 0.20 μg/ml) was significantly decreased. Serum copper was normal. In postnecrotic cirrhosis, mean serum manganese (0.84 ± 0.20 ng/ml) was significantly increased, while copper and zinc concentrations were near normal. Serum zinc was definitely low, however, in 3 cases of advanced cirrhosis (0.62, 0.47, and 0.65 μg/ml, resp.). Manganese, copper, and zinc concentrations in packed blood cells did not show significant variations, with the exception of high manganese values (39.6 and 45.2 ng/g, resp.) found during the active and subsiding phase in a 36-yr-old woman with post-transfusion hepatitis. Positive correlations existed between serum manganese concentrations and serum bilirubin and serum aminotransferase activities in acute and chronic hepatitis and postnecrotic cirrhosis. There also was a highly significant positive correlation between serum aminotransferase activities and serum manganese concentrations.

8781 A CONTROLLED TRIAL OF STEROID THERAPY IN MASSIVE HEPATIC NECROSIS. *(E.)* Ware, A. J.; Jones, R. E.; Shorey, J. W.; Combes, B. (Univ. Texas Southwestern Med. Sch., Dallas). *Am. J. Gastroenterol.* 62(2):130-133, 1974.

An abbreviated, prospective, controlled trial of corticosteroid therapy (i.v. hydrocortisone followed by p.o. prednisolone) in 15 patients with massive hepatic necrosis associated with acute viral hepatitis is reported. Four of the 15 patients were randomly allocated to the steroid group while 11 were selected to receive placebo therapy. The 2 groups were not comparable in some clinical aspects; thus 3 of the 4 steroid-treated patients were more than 30 yr-old while only 2 of 11 placebo-treated patients were of this age. Differences with respect to sex, race and depth of coma at initiation of therapy were also present between the 2 groups. All patients were treated by a standard regimen. The 4 patients treated with corticosteroids all died while 7 of the 11 patients receiving placebo therapy recovered. These findings indicate that, with supportive care alone, a substantial number of patients will recover from this illness. Since the condition is relatively rare, definitive evaluation of the efficacy of steroid therapy in improving this survival rate will require evaluation by a number of centers in cooperation.

LIVER AND BILIARY TRACT

Chronic Hepatitis

8790 HISTOCOMPATIBILITY ANTIGENS IN ACTIVE CHRONIC HEPATITIS AND PRIMARY BILIARY CIRRHOSIS. *(E.)* Galbraith, R. M.; Eddleston, A. L. W. F.; Smith, M. G. M.; Williams, R.; McSween, R. N. M.; Watkinson, G.; Dick, H.; Kennedy, L. A.; Batchelor, J. R. (King's Coll. Hosp. Med. Sch., London, England). *Br. Med. J.* 3(5931):604-605, 1974.

Tissue typing with a standard lymphocytoxicity test and blood grouping were performed on 54 patients with active chronic hepatitis and 45 with primary biliary cirrhosis, all of whom were residents of the southeastern region of England. An additional group of 28 patients with primary biliary cirrhosis from the west of Scotland were also studied with a similar tissue typing method. The frequency of histocompatability antigens HL-A 1 (48%) and HL-A 8 (52%) in the 54 patients with active chronic hepatitis was significantly higher than in 89 control subjects from the same region (22% and 17%, resp.). No correlation was detected with the age and sex of the patients or with the presence of a particular immunological abnormality, but the frequency of HL-A 1 and HL-A 8 was much lower for 9 patients who were positive rather than negative for hepatitis-B-associated antigen. The importance of genetic factors in active chronic hepatitis is implied. In contrast, the frequency of HL-A 1 and HL-A 8 in the 45 patients with biliary cirrhosis from southeast England and the 28 patients with biliary cirrhosis from western Scotland was not significantly different from that found in control groups from the same region.

8791 HISTOLOGICAL CHANGES IN LIVER BIOPSIES FROM PATIENTS WITH CHRONIC HEPATITIS. *(E.)* Christoffersen, P.; Dietrichson, O. (Kommunehosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand. [A]* 82(4):539-546, 1974.

Sequential liver biopsies from 111 patients with verified chronic hepatitis were examined for incidence and degree of various histological qualities. The material was divided into 2 groups: 85 patients exhibiting changes as in chronic aggressive hepatitis and 26 patients with histological changes as in chronic persistent hepatitis. Chronic aggressive hepatitis was characterized by inflammatory infiltration of portal tracts and adjacent parenchyma and by necroses of hepatocytes in the limiting membrane (piece meal necrosis). In addition there were portal fibroses and some degree of bile duct proliferation. Approximately 1/3 of the biopsies with chronic aggressive hepatitis concurrently exhibited atypical bile duct epithelium. The inflammation in chronic persistent hepatitis, unlike that of chronic aggressive hepatitis was virtually confined to the portal tracts. The limiting plates were intact, and parenchymal cell damage was usually slight. The symptoms of chronic persistent hepatitis tended to be indefinite, and it was difficult to be sure whether this type of hepatitis represented a distinct disease process or merely a variant of the histological lesion of late viral hepatitis or chronic aggressive hepatitis. Transition from acute viral to chronic aggressive hepatitis may be suspected if the histological features of acute hepatitis are accompanied by a disproportionate degree of portal inflammation, extensive necrosis at the junctions between the portal tract and lobule, and portal fibrosis. Morphological findings indicate that the prognosis in chronic persistent hepatitis is excellent, whereas the prognosis in chronic aggressive hepatitis is poor, with cirrhosis often developing.

8792 SYPHILIS AND CHRONIC LIVER DISEASE. *(E.)* Harris, J. R. W.; McCann, V.J.; Mahony, J. D. H.; Kennedy, J.; Fulton, T. T. (Roy. Victoria Hosp., Belfast, Ireland). *Br. J. Vener. Dis.* 50(4):267-269, 1974.

Serum samples from 49 patients (19 male and 30 female) with chronic hepatic disease were investigated for evidence of syphilitic infection. Wassermann reactions, Kahn Reiter protein complement-fixations, and fluorescent treponemal antigen absorption (FTA-ABS) tests were performed on the samples. Homogeneous positive FTA-ABS results were obtained for 6 of the patients, and 3 of these 6 were also positive for the Wassermann reaction and the protein complement fixation. Two of the 6 with positive FTA-ABS tests but no other evidence of syphilis were probably false positive. Only 1 of the remaining 4 patients who definitely had syphilis was aware of the diagnosis. None of the 4 had any characteristic clinical signs indicating such infection. Patients diagnosed as having definite syphilis were thought to have either cryptogenic or alcoholic cirrhosis. All of the patients with both syphilis and cirrhosis were male.

8793 THE INCIDENCE OF OXYPHENISATIN-INDUCED LIVER DAMAGE IN CHRONIC NON-ALCOHOLIC LIVER DISEASE. A CONTROLLED INVESTIGATION. *(E.)* Dietrichson, O.; Juhl, E.; Nielsen, J. O.; Oxlund, J.J.; Christoffersen, P. (Kommunehosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(5):473-478, 1974.

Oxyphenisatin acetate provocation (5 mg p.o. twice daily for a maximum of 7 days) was performed with a double-blind cross-over technique in 32 patients (26 females and 6 males, aged 19-84 yr) with chronic non-alcoholic liver disease. The patients were investigated on the 3rd and 7th day of the provocation plus 7 and 14 days after the end of the series. An increase of more than 3 times (200%) the starting values of serum aspartate transaminase or serum bilirubin was considered a significant reaction and cause for immediate discontinuance of the drug. Ten of the patients showed a positive reaction to the drug, with 4 showing more than 200% increases in both serum aspartate transaminase and serum bilirubin on day 3 or day 7 of the provocation. The remaining 6 positives showed more than 200% increase in either one or the other of the 2 serum components measured. Serum values for the transaminase and bilirubin rapidly returned to normal with discontinuation of the provocation. Pain under the right costal margin was experienced by 6 of the patients during the tests. Patients with a positive reaction were those with a long history of high oxyphenisatin intake and those with a long history of active liver disease. Serum bilirubin values prior to provocation were higher in the negative patients. Positive lupus erythematosus cell tests were demonstrated more frequently in the positive-reacting patients (50%) than in the negative group (5%). The results indicate that the use of oxyphenisatin-acetate, a long standing laxative in Denmark, is not justified.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

8794 DEATHS AMONG YOUNG ALCOHOLICS IN THE U.S. NAVAL SERVICE. *(E.)* Schuckit, M. A.; Gunderson, E. K. E. (Navy Med. Neuropsych. Res. Unit, San Diego, Calif.). *Q. J. Stud. Alcohol* 35(3):856-862, 1974.

Demographic characteristics and cause of death are reported for separate samples of all Navy and Marine enlisted men hospitalized for alcoholism between July 1965 and December 1971. The death rate of alcoholics in both services was 15/1000/yr, with the deceased being older and more senior in rank than the average enlisted sailor or Marine. Slightly more than 1/2 of each sample died in the hospital. The percentage of deaths due to liver cirrhosis and pancreatitis among Navy alcoholics was 11 times that of the entire enlisted population (11% *versus* 1%). Liver cirrhosis and pancreatitis accounted for 19% of the deaths among Marine alcoholics as compared to a 1% figure for the entire Marine service. Ulcers accounted for 17% of the deaths among Navy alcoholics and 6% of the deaths among Marine alcoholics (percentage for the entire service in each case was 1).

LIVER AND BILIARY TRACT

Cirrhosis

8796 PRIMARY BILIARY CIRRHOSIS IN SYSTEMIC SCLEROSIS (SCLERODERMA) AND POLYMYOSITIS. *(E.)* Uhl, G. S.; Baldwin, J. L.; Arnett, F. C. (Wilford Hall USAF Med. Ctr, San Antonio, Tex.). *Johns Hopkins Med. J.* 135(3):191-198, 1974.

A case of primary biliary cirrhosis occurring in systemic sclerosis with concomitant polymyositis is reported. The patient was a 48-yr old white woman with long-standing systemic sclerosis (scleroderma) who presented with fatigue, muscle weakness, and abnormal liver and muscle function tests. Hepatic biopsy and the presence of mitochondrial antibodies confirmed the diagnosis of primary biliary cirrhosis. Polymyositis was demonstrated by muscle biopsy. Laboratory findings were: alkaline phosphatase 108 mU/ml, SGOT 195 mU/ml, total bilirubin 0.8 mg%, bromsulfalein retention 13% at 45 min, cholesterol 295 mg%, triglycerides

75 mg%, 5'-nucleotidase 3.4 U, γ-glutamyl transpeptidase 204 U, and hepatitis-associated antigen negative. Total serum protein was 8.7 g% with 4.4 g% globulin; protein electrophoresis showed increased α-2, β, and γ fractions. Quantitative immunoglobulins revealed a very high immunoglobulin M value of 790 mg% (normal 40-180). Serum was trace positive for cryoglobulins. Antimitochondrial antibodies were strongly positive. Creatine phosphokinase was 96 mU/ml (normal 5-30), and electromyograms revealed spontaneous fibrillation and positive sawtooth potentials occurring in short repetitive salvos. The patient was treated with 40 mg of prednisolone on alternate days for the polymyositis. Muscle strength was normal at 16 weeks and creatine phosphokinase was normalized at 25 mU/ml; however, alkaline phosphatase, SGOT, and LDH remained elevated, suggesting ongoing liver disease.

8797 WIDESPREAD ATYPICAL LICHEN AMYLOIDOSUS, PRIMARY BILIARY CIRRHOSIS AND SCLERODERMA.

(E.) Black, M. M. (St. John's Hosp. Dis. Skin, London, England). *Br. J. Dermatol.* 91(Suppl. 10):42-45, 1974.

A case of widespread lichen amyloidosis combined with primary biliary cirrhosis and scleroderma is described. The patient was a 45 yr old female with a history of progressively spreading pruritic papular eruptions. Examination revealed numerous small flat-topped shiny papules in both cubital fossae; these were also present on the flexor aspect of the lower forearms and extensor aspect of the lower legs. Spreading of the eruption to the thighs, dorsa of the feet, hands, and fingers, and soles of the feet was observed at a subsequent examination. Diffuse macular hyperpigmentation of the trunk, limbs, head, and neck was also displayed. Liver biopsy revealed extensive fibrosis and some nodule formation. Bile duct proliferation and moderate acute and chronic inflammatory infiltrate were also noted. Laboratory findings were: hemoglobin 13.8 g, erythrocyte sedimentation rate 75 mm/1 hr, serum bilirubin 1.0 mg/100 ml, serum alkaline phosphatase 85.0 KA U/100 ml, thymol flocculation + + +, serum proteins 8.8 g/100 ml, and a slight increase in $\alpha 2$ and a general increase in γ-globulin. Smooth muscle antibody and anti-nuclear factor were negative, while mitochondrial antibody was positive (greater than 1 in 40). Immunoglobulin G was 2340 mg/100 ml, immunoglobulin A 405 mg/100 ml, and immunoglobulin M 560 mg/100 ml. The patient is believed to be the first reported case of lichen amyloidosus associated with the development of the Kobner phenomenon.

8798 MACROCYTOSIS IN LIVER CIRRHOSIS AND ITS NORMALIZATION DURING THERAPY. *(Ger.)*

Becker, H.; Mosawi, N. (Munic. Hosp., Frankfurt, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79th Congress, 470-473, 1973.

Macrocytosis was studied in 72 cases of histologically confirmed cirrhosis without hemolytic syndrome and iron deficiency in an attempt to discover a pathogenetic relation between cirrhosis and macrocytosis. Macrocytes with cell volume values over $90 \pm 7\ \mu^3$ were considered for the study; the values averaged $103.4 \pm 20.3\ \mu^3$. The macrocyte volume was within the normal range in 26 patients, over 100 μ^3 in 46 cases, over 100 μ^3 in 13 cases, and over 120 μ^3 in 4 cases. The macrocyte cell volume (MCV) values were above average in alcoholics ($112.5 \pm 20\ \mu^3$). There was no significant difference between the degree of anemia in the groups with the lowest and highest MCV values. The hemoglobin level averaged 11.8 g/100 ml in macrocytoses *versus* 12.8 g/100 ml in normocytoses. Because the degree of macrocytosis was not related to the degree of the anemia, it is concluded that pronounced macrocytosis can occur without anemia. Therapy (rest, diet, vitamin B_{12} and folic acid) resulted in a decrease of the MCV value in all 20 macrocytic cases, and values below 100 μ^3 were reached in 7 cases. The hemoglobin level either showed no change or decreased, and increase of the hemoglobin and erythrocyte levels was also observed, indicating the absence of any causal relationship between cirrhosis and anemia. The findings did not reveal the cause of macrocytosis in cirrhosis, but indicate that this condition occurs more frequently than has previously been recognized.

8799 THE INFLUENCE OF PORTOSYSTEMIC SHUNT OPERATION ON IMMUNOGLOBULINS AND Escherichia coli ANTIBODIES IN PATIENTS WITH CIRRHOSIS OF THE LIVER.

(E.) Prytz, H.; Bjorneboe, M.; Johansen, T. S.; Orskov, F. (Bispebjerg Hosp., Copenhagen, Denmark). *Acta Med. Scand.* 196(1/2):109-112, 1974.

Serum γ-globulin levels were determined by paper electrophoresis in 54 patients (27 men and 27 women, mean age 56 yr) with cirrhosis of the liver before and after establishment of a portacaval shunt. A control group of 23 patients operated on for cancer of the lung was studied similarly. A postoperative increase in serum γ-globulin from 18.6 g/liter (prior to shunt operation) to 23.0 g/liter at 7–9 weeks after the operation was observed in the cirrhotics as compared to a mean increase from 12.6 to 13.3 g/liter for controls. Mean albumin values for the cirrhotics decreased from 6.0 g/liter to 5.8 g/liter. Serum immunoglobulins and antibodies to the *Escherichia coli* O group antigens were studied in 2 other groups of patients. One group consisted of 31 patients with cirrhosis and a portacaval shunt, and the other group consisted of 128 cirrhotics without shunt. Average immunoglobulin G and immunoglobulin A values for the patients with portacaval shunts were 24.1 and 5.2, resp., as compared to 19.0 and 4.6 for non-shunt patients. The number of positive antibody reactions in shunt patients was also higher (4.6 mean) in comparison to non-shunt patients (3.3 mean). The γ-globulin increase observed in the first study appears to be related to the change in liver circulation established by the portacaval shunt. The second study supports the conclusion from the first study: the observed changes in immunoglobulins and antibodies are expected if the cirrhotic liver has retained some of the ability of the normal liver to inhibit immunogens.

8800 MATERIAL ISOLATED FROM NORMAL AND VARIANT HUMAN LIVER THAT IMMUNOLOGICALLY CROSS-REACTS WITH ALPHA$_1$-ANTITRYPSIN. *(E.)*

Matsubara, S.; Yoshida, A.; Lieberman, J. (City Hope Natl. Med. Ctr., Duarte, Calif.). *Proc. Natl. Acad. Sci. USA* 71(9):3334-3337, 1974.

A material that strongly reacts with antibodies against α_1-antitrypsin, but has little trypsin inhibitory capacity, was isolated and purified to homogeneity from human liver. Chemically the cross-reacting material is a single chain glycoprotein with a molecular weight of about 18,000, which is significantly lower than that of serum α_1-antitrypsin. The material isolated from the liver of a homozygous variant subject (ZZ) with α_1-antitrypsin deficiency was readily distinguished by electrophoresis from the material extracted from a normal (MM) subject. The tissues from a heterozygous variant subject (MZ) contained both components. The immunologically cross-reacting material is presumably synthesized by the gene that codes for α_1-antitrypsin. The exact biological and structural relations between the cross-reacting material and α_1-antitrypsin are not clear. The material may be part of a precursor for α_1-antitrypsin and, after activation and completion of the molecule, be released from tissues into sera. Alternatively, α_1-antitrypsin may be trapped in tissues after partial degradation and inactivation, resulting in the accumulation of the cross-reacting material in the liver.

8801 HEPATIC NEUROPATHY: A CLINICAL AND ELECTROPHYSIOLOGICAL STUDY. *(E.)* Kardel, T.; Nielsen, V. K. (Gentofte Hosp., Copenhagen, Denmark). *Acta Neurol. Scand.* 50(4):513-526, 1974.

Peripheral nerve function was affected in 31 out of 34 patients (16 female, 18 male, mean age 54 yr) with biopsy-verified liver cirrhosis. Twenty patients had a surgical portacaval shunt. Eighteen patients had a history of chronic alcoholism. Liver biopsies showed a primary biliary cirrhosis in 2 patients. An elevated vibratory perception threshold (VPT) on the big toe was the most common sign of peripheral nerve dysfunction. Nerve function in the arm was also impaired. During ischemia, the rise in VPT (index finger) was delayed in 18 patients. An equivalent slowing of the sensory nerve conduction velocity was recorded in the digit-wrist and wrist-elbow segments of the median nerve, accompanied by a reduction in amplitude and an increase in temporal dispersion of the action potentials. The sensory threshold for electrical stimuli (digit 3) was significantly raised. There was no relationship between neurological findings and routine liver function tests or galactose elimination capacity. Neurological findings occurred with the same frequency in patients with and without chronic alcoholism and in patients with and without a diabetic glucose tolerance test. The distribution of the findings suggests that hepatic neuropathy results from a metabolic inhibition of the nerve axon membrane function.

8802 TREATMENT OF CHRONIC HEPATIC ENCEPHALOPATHY WITH LEVODOPA. *(E.)* Lunzer, M.; James, I. M.; Weinman, J.; Sherlock, S. (Roy. Free Hosp., London, England). *Gut* 15(7):555-561, 1974.

Therapeutic trials with levodopa were conducted on 6 patients (4 males and 2 females, 41-70 yr old) with chronic hepatic encephalopathy with a diagnosis of cryptogenic cirrhosis. All patients had abnormal electroencephalograms and showed clinical evidence of severe neurological impairment. Additionally, they demonstrated a poor response to a low-protein diet, lactulose or neomycin, and colonic exclusion in 2 cases. Three of the patients had previous portacaval anastomoses, while the remaining 3 had natural portal-systemic shunts. Trials were conducted on a double-blind crossover basis after 12 weeks maintenance on levodopa (mean daily dose of 2.1 g/day). Patients were assessed by physical examination, serial electroencephalography, computerized psychometric testing, and measurements of cerebral metabolism and hemodynamics. Definite clinical improvement was noted in 3 of the 6 patients. Gait improved and tremor lessened in 3 patients on levodopa, and coordination improved to a lesser extent in 2 patients. The beneficial effect was not restricted to extrapyramidal functions. Speech was improved in 2 patients, and mood was improved in 3. Only 1 patient was able to tolerate the drug sufficiently long for double-blind assessment. This patient showed marked deterioration when changed to placebo and improvement when recommenced on levodopa. Serial electroencephalography did not demonstrate significant changes in any of the patients, though a significant rise in cerebral oxygen consumption was observed during levodopa therapy. A therapeutic trial of levodopa in patients with chronic hepatic encephalopathy appears indicated when response to conventional therapy is poor.

8803 SERUM ALBUMIN TURNOVER IN LIVER CIRRHOSIS. *(E.)* Bianchi, R.; Mariani, G.; Pilo, A.; Toni, M. G. (2nd Med. Clin., Univ. Pisa, Italy). *J. Nucl. Biol. Med.* 18(1):20-29, 1974.

Albumin catabolism, distribution, and synthesis was observed for 7-23 days in 19 cirrhotic patients, divided into ascitic and nonascitic groups, injected with ^{131}I-human serum albumin (2 μC/kg i.v.). Venous blood samples were obtained 10 min after injection, then at intervals of 1-48 hr, and finally once a day until the end of the experiment. Serum albumin concentration was reduced in both groups but was significantly lower in patients with ascites than in patients without ascites. Intravascular albumin mass was at the lower limit of normal in both groups; the equal size of the intravascular pool in the 2 groups despite the lower serum albumin concentration in patients with ascites was due to the enlarged plasma volume in the latter group. Although extravascular albumin mass was markedly reduced in both groups, it was significantly lower in the ascites group, indicating a marked depletion of intracellular albumin stores. Both fractional and absolute catabolic rates were slightly lower in the patients with ascites. Synthesis rates, determined in 3 patients injected simultaneously with ^{131}I-human serum albumin and sodium ^{14}C-carbonate (150 μC) and 3 days later with ^{14}C-urea (50 μC), were in close agreement with catabolic rates. Liver function tests showed significant correlations between plasma prothrombin content and the absolute catabolic rate of albumin, and between SGOT and the ratio between extravascular and intravascular pool.

8804 THE EFFECT OF CIRRHOSIS ON THE DISPOSITION AND ELIMINATION OF MEPERIDINE IN MAN. *(E.)*

Klotz, U.; McHorse, T. S.; Wilkinson, G. R.; Schenker, S. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *Clin. Pharmacol. Ther.* 16(4):667-675, 1974.

The disposition and elimination of meperidine were compared in drug- and alcohol-free, age-matched groups of 8 normal volunteers (mean age 43 yr) and 10 patients (mean age 46 yr) with liver cirrhosis. The urine was kept at pH 7.0 or more by p.o. administration of 1.8 g of sodium bicarbonate (3 doses, 1 every 2 hr) on the evening prior to the study and every 2 hr during the blood collection period to minimize intersubject variation from variable pH-dependent urinary excretion of meperidine and its pharmacologically-active metabolite normeperidine. Meperidine and normeperidine concentrations in the plasma and urine were determined by gas chromatography, and meperidine plasma concentrations were fitted by an exponential time function. A single rapid i.v. injection of meperidine (0.8 mg/kg) was followed by a biexponential decline of plasma meperidine concentration in normals; the fast and slow disposition rate constants had half-lives of 0.19 hr and 3.2 hr (mean values), resp., in the normal group. The half-life corresponding to the fast disposition rate contant was unchanged in the cirrhotics, but the slow disposition rate constant half-life increased to 7.0 hr. This was associated with a reduction in the total plasma meperidine clearance from 1316 ml/min to 664 ml/min. Data analysis with a 2 compartment open model indicated that meperidine was extensively distributed; initial distribution volume was 1.54 liters/kg, and steady-state volume of distribution was 4.17 liters/kg in controls. Similar distribution volumes were noted in cirrhotics. The overall 1st-order rate elimination rate constant decreased from 6.72 X 10^{-1} /hr in normals to 2.42 X 10^{-1}/hr in cirrhotics. The plasma binding (64.3%) and blood/plasma concentration ratio (6.83 X 10^{-1}) did not differ between normals and cirrhotics. No correlations appeared between the slow disposition rate constant half-life or plasma clearance in cirrhotics and the usual biochemical hepatic function tests. Normeperidine was not detected in the plasma of either group. The elimination of meperidine appears to be prolonged in cirrhosis, probably due to impairment of the liver's drug-metabolizing activity. Caution should be exercised in administering the drug to cirrhotics.

8805 ALTERATIONS IN CIRCULATING THYROID HORMONES AND THYROTROPIN IN HEPATIC CIRRHOSIS: EVIDENCE FOR EUTHYROIDISM DESPITE SUBNORMAL SERUM TRIIODOTHYRONINE. *(E.)*

Chopra, I. J.; Solomon, D. H.; Chopra, U.; Young, R. T.; Chua Teco, G. N. (Univ. Calif. Ctr. Hlth. Sci., Los Angeles). *J. Clin. Endocrinol. Metab.* 39(3):501-511, 1974.

Serum concentrations of thyroid hormones and thyrotropin were studied with radioimmunoassay in 23 clinically euthyroid patients with hepatic cirrhosis (mean age 48 yr). The mean serum total thyroxine concentration was 7.5 μg/100 ml as compared with a normal value 8.4 μg/100 ml. Since the dialyzable fraction of serum thyroxine in the patients was considerably above normal (0.055% *versus* 0.030%), their mean serum free thyroxine concentration of 3.9 ng/100 ml was significantly greater than the mean normal value of 2.8 ng/100 ml. The mean serum concentration of triiodothyronine was 33 ng/100 ml in the patients as compared to a normal mean of 126 ng/100 ml. The mean serum concentration of free triiodothyronine was 163 pg/100 ml as compared to a normal value of 375 pg/100 ml. The mean serum concentration of thyrotropin in the cirrhotic patients was 8.0 μU/ml as compared to a 4.6 μU/ml in normals; it did not differ significantly from that found in newborns (cord serum). The clinical impression of euthyroidism was strengthened by normal serum thyrotropin responses to i.v. administration of thyrotropin-releasing hormone (200 μg) in 5 of 6 patients. Normal Achilles reflex time and an index of myocardial contractility assessed by sphygomorecording also supported the clinical diagnosis of euthyroidism. High normal or high serum free thyroxine concentrations appeared to maintain the euthyroidism in the patients since serum free triiodothyronine concentrations were in the hypothyroid range. Elevated serum free thyroxine was considered a result of a compensatory increase in the activity of pituitary-thyroid axis in response to the low serum free triiodothyronine. Thyroidal secretion of triiodothyronine assessed with a study of serum triiodothyronine responses to thyrotropin-releasing hormone (200 μg i.v.) indicated that thyroid reserve is well maintained in cirrhosis patients. The low serum free triiodothyronine in these patients is probably a result of a substantial reduction in extrathyroidal conversion of thyroxine to triiodothyronine in hepatic cirrhosis.

8806 ACTIVITIES OF KREBS-HENSELEIT ENZYMES IN NORMAL AND CIRRHOTIC HUMAN LIVER. *(E.)*

Khatra, B. S.; Smith, III, R. B.; Millikan, W. J.; Sewell, C. W.; Warren, W. D.; Rudman, D. (Emory Univ. Sch. Med., Atlanta, Ga.). *J. Lab. Clin. Med.* 84(5): 708-715, 1974.

Activities of 5 Krebs-Henseleit (KH) enzymes (carbamyl phosphate synthetase, ornithine transcarbamylase, argininosuccinic acid synthetase, argininosuccinic acid lyase, and arginase) were determined in liver tissue obtained at laparotomy from 17 patients with alcoholic cirrhosis and from 19 persons without liver disease. Specific activities of the 5 enzymes were calculated on the basis of 4 units of reference: wet weight, total N, noncollagen N, and DNA. Specific activities of all 5 enzymes were depressed in cirrhotic liver. The degree of reduction was similar regardless of the unit of reference used to calculate specific activity. Average depression below normal for activity/mg DNA was carbamyl phosphate synthetase, 54%; ornithine transcarbamylase, 37%; argininosuccinic acid synthetase, 50%; argininosuccinic acid lyase, 64%; and arginase, 69%. Rate-limiting enzymes for operation of the KH cycle were carbamyl phosphate synthetase, argininosuccinic acid synthetase, and argininosuccinic acid lyase in both normal and cirrhotic livers. The extent of loss of these 3 enzymes in cirrhotic liver measured *in vitro* correlated with reduction in the maximal rate of urea synthesis and severity of NH_4Cl intolerance measured *in vivo*.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

8811 CELLULAR SITES OF IMMUNOGLOBULINS. V. AN IMMUNOLOGICAL STUDY OF THE HUMAN GALL BLADDER. *(E.)* Chen, S. T.; Tobe, T. (Fac. Med., Kyoto Univ., Japan). *Digestion* 10(3):184-190, 1974.

Gallbladder tissue and bile were obtained during cholecystectomy from 6 male and 9 female patients (27-51 yr old) for radial immunodiffusion studies of immunoglobulins in gallbladder bile and immunofluorescence studies of the distribution of immunoglobulin-containing cells in gallbladder mucosa. All of the patients had cholelithiasis with mild to severe cholecystitis; none had paraproteinemia or blood diseases. Immunoglobulin-containing cells were found to be considerably less numerous in the bile than in the alimentary tract, although immunoglobulin A-containing cells greatly exceeded immunoglobulin M- and immunoglobulin G-containing cells as in the gut. The total number of immunocytes in the gallbladder mucosa was not correlated with the severity of cholecystitis, except for moderately increased numbers of immunoglobulin M-containing cells in empyematous gallbladders. There were, however, increased numbers of immunoglobulin G- and immunoglobulin M-containing cells in muscle layers of severely inflamed gallbladders. Immunoglobulin levels in bile were highly variable and often bore no quantitative relationship to the number of gallbladder immunocytes in contrast to previous intestinal tract findings. Biliary immunoglobulin concentrations appear to be influenced by multiple factors such as variable contributions from the liver, transudation or absorption across inflamed mucosa, and local synthesis and secretion by the gallbladder.

8812 STONES IN COMMON BILE DUCT: NON-OPERATIVE MANAGEMENT. *(E.)* Mok, H. Y. I.; Bell, G. D.; Whitney, B.; Dowling, R. H. (Roy. Postgrad. Med. Sch., London, England). *Proc. R. Soc. Med.* 67(7):658-660, 1974.

The non-operative management of stones in the common bile duct with cholic acid infusion therapy is reported. The patient was a 62-yr-old male who had undergone cholecystostomy with removal of multiple small gall stones and subsequent cholecystectomy. On the latter occasion a stone was also removed from the common bile duct which was dilated. A subsequent T-tube cholangiogram showed another stone in the common hepatic duct. The patient was re-admitted for common bile duct stone dissolution therapy. Treatments with saline infusion (500 ml 0.9% sodium chloride/12 hr) for 1 week and heparin infusion (50,000 U in 500 ml saline/12 hr) for 1 week were unsuccessful. Treatment with cholic acid infusion (100 mM solution, 30 ml/hr) plus cholestyramine (4 g/2 hr p.o.) to control diarrhea, resulted in an attack of severe upper abdominal pain and vomiting after 2 days. A T-tube cholangiogram 5 days later showed a normal common bile duct with disappearance of the stone. A subsequent cholangiogram 1 week later was also normal. Follow-ups 1 and 3 months later indicated good physical condition and normal liver function tests. Cholic acid infusion therapy was also used to treat 3 other patients with retained common bile duct stones. The treatment was successful in 1 of the 3 patients.

8813 DISSOLUTION OF GALLSTONES WITH BILE SALTS, LECITHIN, AND HEPARIN. *(E.)* Cheung, L. Y.; Englert, Jr., E.; Moody, F. G.; Wales, E. E. (Univ. Utah Med. Ctr., Salt Lake City). *Surgery* 76(3):500-503, 1974.

In vitro experiments were performed to evaluate the solubility of human cholesterol gallstones in various bile salt solutions (physiological concentration) with and without the addition of lecithin and heparin. Gallstones were collected during surgery with a sterile technique and placed in the patient's own bile. Gallstones of similar size and weight obtained from the same patient were placed in 10 ml of 150 mM sodium phosphate buffer solution (pH 8) containing one of the salts (100 mM) with and without lecithin and heparin for incubation at 37 C. Unconjugated deoxycholate (100 mM) with lecithin solution (100 mM) was the most effective solution for dissolving human cholesterol gallstones. The addition of heparin at a concentration of 1000 U/10 ml did not increase the solubilizing capacity of deoxycholate. Optimal dissolution of gallstones required renewal of the solutions. Unconjugated deoxycholate with lecithin appears to be potentially useful as an effective infusate for retained bile duct stones; its toxicity by T-tube infusion at this concentration, however, is unknown and warrants further study.

8814 SUPERSATURATED BILE — IS IT DUE TO A METABOLIC DISORDER OR TO AN IMPAIRED GALLBLADDER? *(E.)* Schersten, T.; Cahlin, E.; Jonsson, J.; Lindblad, L.; Nilsson, S. (Sahlgrenska Hosp., Univ. Goteborg, Sweden). *Scand. J. Gastroenterol.* 9(5): 501-506, 1974.

Biliary lipid composition during various bile acid secretion rates was determined in 15 patients (9 women, median age of 43 yr; 6 men, median age of 56 yr) operated on for uncomplicated gallstone disease. Bile acid secretion rate was varied by enterohepatic circulation interruption with a balloon catheter and by duodenal refeeding of bile acid conjugates in Ringer's solution. The hepatic bile varied from being unsaturated or saturated to being supersaturated with cholesterol, at bile acid secretion rates of 1300 ± 300 μM/hr. The diurnal variation of biliary lipid composition was studied in another 10 cholecystectomized patients. Night bile from fasting patients was supersaturated with cholesterol. Lipid composition and diurnal variation were similar in 7 of the patients. These patients secreted supersaturated bile for a mean of 13 hr out of the 24; 2 patients secreted supersaturated bile throughout the 24 hr. A low bile acid secretion rate appears capable of causing supersaturation of hepatic bile with cholesterol. Also, a functioning gallbladder does not appear essential for continuous production and secretion of supersaturated bile.

8815 CANALICULAR BILE SECRETION IN MAN. STUDIES UTILIZING THE BILIARY CLEARANCE OF $[^{14}C]$ MANNITOL. *(E.)* Boyer, J. L.; Bloomer, J. R. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Clin. Invest.* 54(4):773-781, 1974.

Bolus injections of 50 μC of sterile ^{14}C-mannitol were administered i.v. (in 250 mg of unlabeled mannitol) to 5 postcholecystectomy patients (3 women and 2 men, 20-71 yr old) with indwelling T-tubes and reestablished enterohepatic circulations to evaluate the biliary clearance of labeled mannitol as an indicator of canalicular bile flow. Labeled mannitol appeared in collections of bile 9 to 22.5 min after i.v. injection, rose to a peak, and thereafter paralled the plasma ^{14}C-mannitol disappearance curve. Bile-plasma labeled mannitol ratios and labeled mannitol clearances were determined during control and choleretic periods after correction of the bile ^{14}C-mannitol points for the transit time of a given sample. Injection of sodium dehydrocholate (5 ml i.v.) resulted in proportionate increases in bile flow and mannitol clearance. However, when ductular secretion was stimulated with i.v. bolus of secretin (75-90 U) in other studies, labeled mannitol clearance remained essentially unchanged, indicating that ^{14}C-mannitol entered bile at the level of the hepatocyte and could be utilized as a marker of canalicular flow in man. During control studies when bile drained spontaneously from biliary fistulas in fasting patients, bile plasma ^{14}C-mannitol ratios averaged 0.62 ± 0.12 ml/min. When the rate of bile flow was plotted as a function of bile salt excretion after correction for the effects of biliary dead space, linear regression analysis revealed that approximately 7 μliter of bile was secreted with each μM of bile salt. Estimates of bile salt-independent canalicular flow accounted for at least 1/3 of the estimated 24-hr bile production (604 ml) in these patients, indicating that this fraction of canalicular flow is a significant source of bile secretion in man.

8816 BILE DUCT PRESSURE AND CARDIAC SYMPTOMS. *(E.)* Geisler, F.; Dona, G.; Shapira, J.; Gutman, A. (Donolo Gov. Hosp., Jaffa, Israel). *Israel J. Med. Sci.* 10(6):677-679, 1974.

The effect of varying bile duct pressure on cardiac functions was studied in 12 unanesthetized patients (10 female and 2 male, average age 47 yr) who had undergone cholecystectomy and T-tube drainage 15-20 days earlier. The pressure in the common bile duct was increased through a T-tube with an insufflation apparatus, and an electrocardiogram was recorded simultaneously. Blood pressure and pulse were also monitored continuously. No changes in any of the cardiac parameters were observed during the bile duct pressure increases. The patients complained of some discomfort in the bile duct area, though immediate relief was experienced with pressure decrease. No discomfort or complications occurred following the examination. Although cholelithiasis and cholecystitis are frequently reported to be associated with cardiac symptoms, the present findings indicate no association between an increase in bile duct pressure and cardiac symptoms.

8817 DYNAMICS OF THE ENTEROHEPATIC CIRCULATION OF BILE ACIDS. POSTPRANDIAL SERUM CONCENTRATIONS OF CONJUGATES OF CHOLIC ACID IN HEALTH, CHOLECYSTECTOMIZED PATIENTS, AND PATIENTS WITH BILE ACID MALABSORPTION. *(E.)* LaRusso, N. F.; Korman, M. G.; Hoffman, N. E.; Hofmann, A. F. (Mayo Clin., Rochester, Minn.). *N. Engl. J. Med.* 291(14):689-692, 1974.

The effect of 3 liquid meals (corn oil, dextrose, and 300 ml Meritene) on the serum level of cholic acid conjugates was determined with radioimmunoassay in 8 healthy subjects, 5 cholecystectomized patients, and 6 patients with bile acid malabsorption. In the 1st group (6 men and 2 women, mean age 36.4 yr), the bile acids peaked 90-120 min after each meal and returned to baseline by 4 hr. Maximal postprandial increases for each patient were large (200-1000% increase above baseline). The pattern was meal related as indicated by the fact that bile acid values remained at [illegible] ine in 4 subjects undergoing a 22-hr fast. In [illegible] and 4 women, mean age 55.4 yr) cholic acid conjugates increased to lower maxima after the 1st meal and then remained elevated throughout the day, returning to base line 14 hr after the evening meal. Cholic acid conjugate serum concentrations increased to a maximum at 75-105 min after the initial test meal. After the initial meal, the maximum for each patient was small (100-400% increase above base line) as compared to healthy subjects. In the 3rd group (1 man and 5 women with ileal resection, mean age 42.5 yr), the postprandial maxima were small (50-250% above base line) in comparison to the healthy subjects. The time between the ingestion of the initial test meal and maximal postprandial increase was significantly shorter (75 min in 2 patients and 90 min in 4 patients). There was no correlation between the length of ileum resected or amount of steatorrhea and the fasting or postprandial levels of cholic acid con[illegible]s. The observations indicate that serum cholic acid conjugate determinations can be used to investigate the dynamics of the enterohepatic circulation of bile acids. The determination of postprandial levels [illegible] acid conjugates may prove to be a simple, [illegible] and valid test of bile acid malabsorption.

SPHINCTEROPLASTY FOR POSTCHOLECYSTECTOMY SYNDROME.

(E.) Taft, D. A.; Wreggit, G. R. [illegible] nia Mason Med. Ctr., Seattle, Wash.). *Am. Surg.* [illegible] 527-530, 1974.

Criteria for diagnosing stenosis of the sphincter of Oddi in cholecystectomy patients were reviewed based on statistics from 12 patients undergoing transduodenal sphincteroplasty for the condition. A normal or [illegible] htly dilated common duct was noted in this [illegible] patients and was not amenable to choledoch[illegible]nostomy. Extensive sphincteroplasty, implying [illegible] ete division of the sphincter mechanism, was used. Criteria to be met before diagnosis of stenosis of the sphincter of Oddi is considered and sphincteroplasty undertaken include: a history suggestive of postcho[illegible]my syndrome; and elevated levels of alkaline phosphatase, SGOT, amylase, or bilirubin either following an attack or induced by morphine. SGOT was the most sensitive indicator in the 12 cases presented, [illegible] elevated in the majority. Preoperative i.v. [illegible] ngiograms carried out in 8 patients were not helpful. An operative cholangiogram was performed in all cases, and 6 of the cases showed distal stenosis of the duct. Normal operative cholangiograms were obtained in 5 cases, while only 2 showed dilatation. Choledochotomy and transverse duodenotomy were carried out in each patient regardless of roentgenographic evidence. The ampullae and sphincter lumen size were directly calibrated with Bakes dilators. The sphincter measured 3 mm or less in all cases; in the majority of cases even a 1 mm probe passed only with difficulty or not at all. Extensive sphincteroplasty (2-3 cm in length) was then performed, taking [illegible]t care to connect the duodenal mucosa to the common duct mucosa without impinging on the pancreatic duct or its orifice.

8819 DISAPPEARANCE OF PHENAZONE FROM PLASMA IN PATIENTS WITH OBSTRUCTIVE JAUNDICE.

(E.) Elfstrom, J.; Lindgren, S. (Surg. Clin., Univ. Linkoping, Sweden). *Eur. J. Clin. Pharmacol.* 7(6):467-471, 1974.

Gas chromatography (4'-methylphenazone internal standard) was used to determine the plasma half-life of phenazone in 2 groups of patients surgically treated for obstructive jaundice. The elimination rate of the drug reflects the ability of the liver to hydroxylate it and possibly other drugs as well. The cause of jaundice in 1 group of 11 patients (7 women and 4 men, 21-77 yr old) was a stone in the common bile duct. Studies were performed on these patients both during the icteric period and 3 months later following obstruction relief and return of plasma bilirubin to normal. A separate group of 5 patients (4 women and 1 man, 55-72 yr old) with jaundice due to malignant disease was studied only once. Statistical analysis of the phenazone elimination rates failed to show a uniform correlation between such rates and obstructive jaundice. The excretion of phenazone in the bile of 2 non-icteric patients was less than 2% of the dose administered. The ability of the liver to hydroxylate phenazone does not appear to be significantly altered in patients with obstructive jaundice of the degree usually encountered in the surgical clinic.

8820 PROLONGED OBSTRUCTIVE JAUNDICE AND HAEMANGIOMATOSIS.

(E.) Sardemann, H.; Tygstrup, I. (Rigshosp., Copenhagen, Denmark). *Arch. Dis. Child.* 49(8):665-667, 1974.

Two cases of prolonged obstructive jaundice and hemangiomatosis of the skin are reported for infants admitted at 3 weeks and 2 weeks of age. Neither case had a family history of jaundice or vascular tumors. One of the deliveries was uncomplicated, while the other was by cesarean due to fetal distress. The following common features were observed in both patients: walnut-sized placental hemangiomas in combination with several cutaneous hemangiomas which increased in size during the 1st and 2nd weeks and spontaneously regressed after the 4th and 5th week of age; and prolonged jaundice of the obstructive type which reached maximum severity during the 2nd and 3rd week and thereafter regressed concomitantly with the disappearance of the hemangiomas and the hepatomegaly. Although hemangiomas in the porta hepatis were not observed in the 2 patients, it seems probable that hemangiomas obstructed the main bile ducts and that obstruction disappeared when the tumors regressed. The cases reported provide additional grounds for delaying exploratory laparotomy to observe if spontaneous recovery will occur.

8821 TREATMENT OF ACUTE CHOLECYSTITIS BY ROUTINE URGENT OPERATION.

(E.) Salleh, H. B. M.; Balasegaram, M. (Gen. Hosp., Kuala Lumpur, Malaysia). *Br. J. Surg.* 61(9):705-708, 1974.

Diagnostic, operative, morbidity, and mortality data are presented for 218 cases of acute cholecystitis which were routinely treated by urgent cholecystectomy within 12 hr of hospital admission. Diagnosis of acute cholecystitis was made on the basis of plain radiography, symptomatology, and various physical signs. Pain in the epigastrium and/or right hypochondrium was the most common symptom, being present in 95% of the cases. Tenderness in the right hypochondrium and/or epigastrium was the most common sign (90% occurrence). Radiographic results were positive in 62% of the cases. The most frequent radiographic finding was a vague haziness in the right hypochondrium (84 cases), while enlargement of the gallbladder shadow (43 cases) was the next most common finding. Operative findings revealed a diagnostic error of 1.4% (3 cases out of 218). Fewer stones were seen on plain x-rays of the abdomen than were actually found during surgery due to overlying gas shadows, the smallness of some calculi, and the radiolucent quality of some calculi. There was one mortality, a 48-yr old woman who died on the 6th postoperative day from a massive acute myocardial infarction. Wound infection was the commonest postoperative complication, occurring in 15 patients. Paralytic ileus was the next most common (12 cases). A short segment of the cystic duct had to be left behind in 2 patients due to extreme edema and an indefinite outline of the junction between the cystic, common hepatic, and common bile ducts. A deep laceration of the liver occurred in 1 patient with empyema of the gallbladder. Average hospital stay was 9 days. Recurrence of biliary tract disorders occurred in 2 cases.

8822 EXOCRINE FUNCTION OF THE LIVER AND PANCREAS IN PATIENTS WITH CHRONIC CHOLECYSTITIS.

(Rus.) Serediuk, N. N; Barbenko, N. A.; Denisiuk, V. G.; Neiko, E. M. (Ivano-Frankovsk Med. Inst., USSR). *Vrach. Delo* (9):95-98, 1974.

Exocrine function was studied in 67 patients with chronic cholecystitis by determining the bile acid, cholesterol, and bilirubin content in gallbladder and hepatic bile. In 44 patients the total bile acid content was 795 ± 55.3 mg (normal 300-800 mg), and in 23 patients 255 ± 24.4 mg. The analysis of the data revealed biliary insufficiency in 34.3% of the patients. The cholate-cholesterol index was found to be lower both in patients with normal bile secretion and in those with biliary insufficiency. Analysis of the exocrine pancreas showed reduced bicarbonates and increased enzyme formation in patients with normal bile secretion, while lower enzyme activity was observed in patients with biliary insufficiency.

8823 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHIC EVALUATION OF SCLEROSING CHOLANGITIS. *(E.)*

Lefton, H. B.; Winkelman, E. I. (Cleveland Clin., Ohio). *Cleve. Clin. Q.* 41(3):143-147, 1974.

The use of endoscopic retrograde cholangiography for assessing patients with primary sclerosing cholangitis is illustrated by a case report of a 37-yr-old man re-admitted for symptoms of occasional malaise subsequent to a cholecystectomy performed 3 yr earlier. Liver function studies a month prior to the 2nd admission disclosed the following values: total serum bilirubin 2.1 mg/100 ml; BSP retention 26 mg/100 ml at 45 min; alkaline phosphatase 270 IU; and SGOT 115 Karman U. A skin biopsy was obtained and a diagnosis of porphyria cutania tarda was made. No history of jaundice, pleuritis, or recent change in color of urine or stool were reported. Upon admission an intravenous cholangiogram gave inadequate visualization of the bile duct system. Retrograde cannulation of the ampulla of Vater was performed, and the cholangiograms showed severe hypoplasia and beading of the biliary ducts as well as narrowing of the common bile duct. These changes are compatible with sclerosing cholangitis. The postcannulation course was complicated by gram-negative sepsis with *Enterobacter cloacae* which responded to cephaloridine and gentamicin. Before the patient's discharge, a liver biopsy specimen showed minimal bile stasis with no evidence of acute inflammation. No evidence of γ-A globulin, γ-M globulin, or γ-G globulin was found during immunofluorescence studies of the skin and liver biopsies. The patient was referred to his family physician for follow-up; 1 yr later, without treatment, total serum bilrubin level was 2 mg/100 ml with a direct bilirubin of 0.3 mg/100 ml. The patient had no symptoms except for occasional malaise at the end of the day. The major problem in diagnosing sclerosing cholangitis is differentiating it from carcinoma of the bile ducts; this can be adequately done only by long-term follow-up.

8824 BILE MUCOIDS IN BILIARY TRACT DISEASES.

(Rus.) Sheleketina, I. I.; Leliukhina, E. V. (Dnepropetrovsk Res. Inst. Gastroenterol., USSR). *Vrach. Delo* (8):39-43, 1974.

Biochemical studies of mucoids were made in 27 normal subjects and 90 patients with chronic cholecystitis (23 cases), calculous cholecystitis (28), and postcholecystectomy syndrome (39). The total content of hexosamines, glycoproteins, and hyaluronic acid was determined. Findings indicated that the hexosamine content in hepatic bile shows an average increase of 2-2.8 times normal in bile duct diseases. Patients with calculous cholecystitis and postcholecystectomy syndrome accounted for 75% of cases with elevated hexosamine content. It was found that 69.5% of patients with elevated hexosamine content in C bile exhibited dyscholia involving a drop in the bile acid content, phospholipids and lipid complex, along with an increase in cholesterol and bilirubin. It is suggested that bile mucoids contribute to the growth of gallstones by increasing bile viscosity.

8825 CONGENITAL ABSENCE OF THE GALLBLADDER: REVIEW OF THE LITERATURE AND REPORT OF A NEW CASE. *(E.)*

Langley, J. R.; Hull, D. C. (no affil.). *Am. Surg.* 40(9):548-551, 1974.

A case report of agenesis of the gallbladder is presented along with a literature review of previous cases. A 32-yr-old Negro woman with a 1-week history of epigastric pain, nausea, yellowing of the skin and eyes, and passage of dark urine was admitted for physical examination. Laboratory data included the following: total bilirubin 12.4 mg %; blood glucose 110 mg %; serum amylase 139 U; SGOT

1260 mU/ml; SGPT 755 IU/ml; alkaline phosphatase 186 mU/ml; and LDH 362 IU/ml. The presumed diagnosis was common duct obstruction due to a stone which had passed. Repeated oral cholecystograms failed to show the gallbladder. When laboratory values returned to normal, the patient was admitted for cholecystectomy, with the presumed diagnosis of cholecystitis with cholelithiasis. The undersurface of the liver was explored and no gallbladder found. A liver scan further documented the absence of a gallbladder. An operative cholangiogram performed with Hypaque showed the common duct and liver radicles to be normal. Biopsy of the free edge of the right liver lobe revealed normal liver tissue. The patient was discharged 1 week after operation and has had no specific problems to date. A review of reported incidences of agenesis of the gallbladder indicates that 1/2 or more of such patients show preoperative evidence suggestive of cholecystic disease. The mechanism of pain and jaundice in cases not associated with choledocholithiasis is unknown.

GENERAL

8836 ZOLLINGER-ELLISON SYNDROME. ULTRASTRUCTURAL AND HISTOCHEMICAL OBSERVATIONS IN A CHILD WITH ENDOCRINE TUMORLETS OF GASTRIC ANTRUM. *(E.)* Bhagavan, B. S.; Hofkin, G. A.; Woel, G. M.; Koss, L. G. (Sinai Hosp., Baltimore, Md.). *Arch. Pathol.* 98(4):217-222, 1974.

A case of Zollinger-Ellison syndrome associated with multifocal hyperplasia (tumorlets) of gastric antral endocrine cells was found in an 11-yr-old boy. The tumorlets were located predominantly within the lamina propria and were composed of uniform cells with vesicular round nuclei and well-defined cystoplasmic membranes. The pattern and arrangement of these cells resembled carcinoid-islet cell tumors. Cells of small nodules showed transition to cells in the bottom and midportions of the pyloric gland. Similar tumorlets were present in the resected proximal duodenum, but no evidence of abnormality was found in the subtotally resected pancreas. Histochemical analysis indicated that the component cells of the tumorlets had many features in common with gastrin-containing G cells. The cells were nonreactive to argentaffin stains, to toluidine blue metachromasia, and to the Bodlian and modified Davenport silver stains. Areas of cell proliferation were argyrophilic with the Bodlian technique, whereas the centers of the tumors were nonargyrophilic. Therefore, while the centers of the tumorlets are closely related to G cells, the diffuse cell hyperplasia may belong to 1 or more members of the wide spectrum of enterochromaffin-argryophilic cell systems of the stomach and intestinal tract. The ultrastructure of the G cells demonstrated secretory granules of 150-300 mμ in diameter. Persistent postoperative hypergastrinemia (45,000 pg/ml serum gastrin) and hyperserotoninemia (0.48 μg/ml serotonin) was thought to be related to residual tumorlets in the part of the duodenum or jejunum left *in situ*.

8837 GASTRIC ENDOCRINE CELL PROLIFERATION: ASSOCIATION WITH ZOLLINGER-ELLISON SYNDROME. *(E.)* Bordi, C.; Cocconi, G.; Togni, R.; Vezzadini, P.; Missale, G. (Inst. Pathol. Anat., Univ. Parma, Italy). *Arch. Pathol.* 98(4):274-278, 1974.

A proliferation of endocrine cells was observed in the fundic-type mucosa (oxyntic gland area) of the stomach of a 32-yr-old man with the Zollinger-Ellison syndrome. The cells did not contain gastrin, as shown by immunofluorescence and tissue immunoassay. The cells were located along the basement membrane of the glands and often formed a continuous layer. Their ultrastructure was similar to that of the so-called enterochromaffin-like cells. Small secretory granules, membrane-limited vacuoles with a small dense core, parallel array of rough endoplasmic reticulum cisternae, and numerous mitochondria were evident. On light microscopy, the proliferated cells were stained by the silver methods of Grimelius and Sevier-Munger and differed from the true enterochromaffin cells because of the lack of the argentaffin reaction, diazo reaction, and formalin-induced autofluorescence. The frequency of argyrophil cells of gastric body mucosa was significantly greater in the patient than in 20 other patients with gastric ulcer, duodenal ulcer, or gastric cancer.

8838 ACUTE GASTROENTERITIS ASSOCIATED WITH REOVIRUS-LIKE PARTICLES. II. *(E.)* Flewett, T. H.; Davies, H.; Bryden, A. S.; Robertson, N. J. (East Birmingham Hosp., England). *J. Clin. Pathol.* 27(8):608-614, 1974.

Virus particles resembling reoviruses or orbiviruses were found in feces from 40 of 73 patients under 6 yr with acute gastroenteritis and in feces from only 1 (a 20-yr-old man) of 59 gastroenteritis patients over 6 yr. Among 89 patients admitted with diagnoses other than gastroenteritis, the virus particles were present only in the feces of two 1-month-old infants with Hirschsprung's disease and "unsatisfactory development", resp. Morphologically the particles resembled orbiviruses more than reoviruses, but they differed from the orbiviruses in having a smooth, circular outline with a well-marked continuous rim as seen in negatively stained preparations. The particles could not be agglutinated by antisera to reovirus types 1, 2, and 3. They may be members of a new group of double-stranded RNA (diplorna) viruses.

8839 COMPARISON OF THREE AGENTS OF ACUTE INFECTIOUS NONBACTERIAL GASTROENTERITIS BY CROSS-CHALLENGE IN VOLUNTEERS. *(E.)* Wyatt, R. G.; Dolin, R.; Blacklow, N. R.; DuPont, H. L.; Buscho, R. F.; Thornhill, T. S.; Kapikian, A. Z.; Chanock, R. M. (Lab. Infect. Dis., Natl. Inst. Allergy and Infect. Dis., Bethesda, Md.). *J. Infect. Dis.* 129(6): 709-714, 1974.

Two family outbreaks of acute infectious nonbacterial gastroenteritis occurring in Hawaii and Maryland are reported. Symptoms consisted of headache, malaise, anorexia, nausea and vomiting and diarrhea. Recovery was complete without sequelae. Stool ultrafiltrates from these patients reproduced the symptoms following inoculation into healthy volunteers. Similar symptoms were also produced by inoculations of filtrates containing the previously described viral Norwalk agent. Cross challenge studies of subjects with Norwalk agent and one of the two new agents indicated that the Norwalk and Hawaii agents were antigenically dissimilar whereas the Norwalk and Maryland agents were related.

8840 ACRODERMATITIS ENTEROPATHICA. A CLINICAL AND BIOCHEMICAL SURVEY. *(E.)* Neldner, K. H.; Hagler, L.; Wise, W. R.; Stifel, F. B.; Lufkin, E. G.; Herman, R. H. (Univ. Colorado Med. Ctr., Denver). *Arch. Dermatol.* 110(5):711-721, 1974.

A 21-yr-old girl with acrodermatitis enteropathica has been successfully treated with diiodohydroxyquin (650 mg 1-4 times/day) since age 18 months. The major continuing consequence of her disease was occasional mild diarrhea. Trial periods without diiodohydroxyquin resulted in erythematous dermatitis of her hands, feet, and face with secondary bacterial infection. To determine possible causes of the disease and the reasons for the efficacy of diiodohydroxyquin, controlled studies on a metabolic ward were carried out over a 2 1/2 yr period, both with and without diiodohydroxyquin treatment. The proposed defect in tryptophan metabolism reported in the literature could not be verified: urinary excretion of tryptophan metabolites following a standard p.o. tryptophan load, with or without pyridoxine stimulation, was essentially normal. Diiodohydroxyquin did not substantially affect tryptophan metabolism. Jejunal glycolytic enzymes showed a normal adaptive response to changes in diet and p.o. folic acid; in the patient and some controls, glycolytic enzyme activity increased with diiodohydroxyquin treatment. When the patient was not receiving diiodohydroxyquin, electron microscopy demonstrated abnormal jejunal cytoplasmic inclusions in the fasting state. Serum lipids were consistently low, and lipoprotein electrophoresis showed hypobetalipoproteinemia. Arachidonic acid levels were repeatedly low but reached their lowest value while the patient was not taking diiodohydroxyquin. The results suggest that a defect in fatty acid metabolism is implicated in acrodermatitis enteropathica. Since 2 prostaglandins are derived from arachidonic acid, prostaglandins could be the final mediators of the clinical expression of the disorder.

8841 ACRODERMATITIS ENTEROPATHICA ASSOCIATED WITH LOW DENSITY LIPOPROTEINS DEFICIENCY.

(E.) Wallis, K.; Azizi, E.; Kook, A. J.; Herczeg, E.; Julsary, A.; Szeinberg, A.; Zaidman, J. L. (Asaf Harofe Gov. Hosp., Zerifin, Israel). *Clin. Pediatr.* 13(9):749-754, 1974.

The propositus, a male infant (age 1 month), was hospitalized with acute diarrhea. He was born to healthy unrelated parents of Libyan origin. Pregnancy had been normal. He had 2 healthy sisters, aged 10 and 5 yr. One other infant boy had died at 3 months of age some years earlier from acute gastroenteritis of unknown origin, after hospitalization for malnutrition with severe diarrhea. During hospitalization, i.v. fluids were given to correct severe dehydration and acidosis. Various antibiotics were administered. Diarrhea and vomiting persisted and dermatologic changes noted near and at the angles of the mouth, on the chin, cheeks, left ear, neck, fingers, thighs, sacral region, exterior surfaces of the elbows, and on the scrotum progressed. Levels of different lipid components were low and remained so due to complete absence of β-lipoproteins as demonstrated by paper and cellogel electrophoresis. During the 2nd month of hospitalization, acrodermatitis enteropathica was diagnosed. Diiodoquine treatment (55.5 mg, 4 times/day for 5 days) gave no improvement. The dose was raised to 210 mg, 4 times/day; no improvement followed and death occurred on the 67th day after hospitalization. Autopsy showed pronounced degrees of atrophy in the small and large intestine. In the small intestine the mucosal villi were broad and not sharply delineated. The mucosa of the large intestine showed Lieberkuhn's crypts rare and straight. Vacuoles in the epithelium of the small intestine of the type present in β-lipoproteinemia were not found. After the propositus' death, another sister, now 6 months of age, was born. Serum lipoprotein electrophoretic studies performed on the younger sister at 1 1/2 months of age showed almost total absence of low density lipoprotein fractions. The electrophoretic pattern of other family members was normal with the exception of the father. Immunodiffusion studies indicated that all family members, including the infant girl, contain antigenically reactive β-lipoproteins. Electrophoretic analysis of the serum lipoproteins of this infant at 2 1/2 and 3 1/2 months show increased proportions of the serum low density lipoproteins. The values for total lipids and various fractions showed that the infant girl's serum had very low levels of total serum lipids, phospholipids, total cholesterol, and, in particular, total triglycerides. A content of triglycerides above normal levels was found in the father's serum. This may be the 1st time that a complete absence of antigenically reactive serum β-lipoproteins has been described in a disease other than αβ-lipoproteinemia.

8842 YERSINIOSIS AS AN INTERNAL DISEASE.

(E.) Leino, R.; Kalliomaki, J. L. (Dept. Med., Univ. Turku, Finland). *Ann. Intern. Med.* 81(4):458-461, 1974.

From 1971-1973, 60 patients were hospitalized for an infectious disease caused by *Yersinia enterocolitica* serotypes II and IX or *Yersinia pseudotuberculosis* serotype I. At the same time 65 patients with similar symptoms were treated as outpatients. Diagnosis was based mainly on elevated antibody titers against these microorganism: 43 cases of infection were caused by *Y. enterocolitica* II, by *Y. enterocolitica* IX, and 4 by *Y. pseudotuberculosis*. The most prominent symptoms were fever (43 cases), diarrhea (27), abdominal pains (20), erythemia nodosum (11), and arthritis (33). One patient was 1st operated on for suspected acute appendicitis; 1 developed chronic colitis, and another had acute glomerulonephritis, both possible caused by yersiniosis. One patient had mild hepatitis and 4 showed electrocardiographic signs of mycocarditis although no murmurs were heard. All patients were treated with antibiotics (tetracyclines or a combination of trimethoprim and sulfamethoxazole. In most cases synovial edema disappeared after a few months with the exception of 2 patients with synovial effusion in the knee as late as 1 yr after treatment. Many patients reported very prolonged arthralgia. The data suggest that some patients previously diagnosed as having rheumatic fever actually had yersiniosis.

8843 ALIMENTARY TRACT METASTASES FROM MALIGNANT MELANOMA.

(E.) Beckly, D. E. (Bristol Hosp., England). *Clin. Radiol.* 25(3):385-389, 1974.

Radiologic findings are presented for 3 patients with alimentary tract metastases from malignant melanoma. A 31-yr-old man presented with malaise, anorexia, and weight loss associated with epigastric discomfort. An axillary malignant melanoma had been exercised 7 months earlier, although no primary site was found. Barium enema examination showed a large filling defect in the stomach with a central collection of barium within the mass. Coarse mucosal folds were present in the remainder of the stomach. The histology was that of an anaplastic tumor. Laparotomy revealed a large gastric mass and another tumor in the jejunum; histologically, this tumor was a nonpigmented melanoma. On the 7th day after a Polya gastrectomy and local jejunum resection, the patient died from a massive intra-abdominal hemorrhage. Autopsy showed metastatic melanoma in the brain, lungs, and jejunum. An 88-yr-old man presented with ankle edema, shortness of breath, and vomiting. A malignant melanoma had been excised from the neck the previous yr. Barium meal examination showed filling in the 1st part of the duodenum with re-entrant angles at the junctions with the duodenal wall. No central collections of barium were identified. The patient's poor condition did not permit surgery. Autopsy revealed bronchopneumonia and metastatic melanoma in the duodenum, ileum, and transverse mesocolon. Presenting symptoms in a 56-yr-old man were lethargy, shortness of breath, and vague epigastric discomfort. His history included excision of a malignant melanoma from the back 2 yr previously and subsequent reccurrence at the primary site and in the axilla. Barium examination indicated a deformed duodenal cap, widening of the lumen, and rounded filling defects in the 2nd part of the duodenum. Several filling defects showed re-entrant angles at their junction with the duodenal wall. A duodenal ulcer was found at autopsy together with numerous tumor masses in the duodenum, jejunum, and upper ileum. Histologic examination confirmed malignant melanoma. In patients with multiple gastrointestinal lesions and history of a previous malignant melamona, metastases should be suspected and a search should be made for metastases at other sites. In the case of a single gastrointestinal lesion, diagnosis should be based on biopsy as well as barium studies.

8844 INHIBITION OF GASTRIC ACID SECRETON BY EXTRACT OF WDHA TUMOR.

(E.) Vogel, T. T. (Ohio State Hosp., Columbus). *Am. J. Surg.* 128(5): 657-658, 1974.

Transplantation of the antrum to the transverse colon produced gastric hypersecretion in rats. Over a 2-hr collection period, acid output almost tripled compared with control values and volume almost doubled. Acid extracts of a watery diarrhea hyperchloremia achlorhydria (WDHA) tumor (2.5 mg/kg s.c.) reduced acid output by 40%. Secretin (75 U/kg) reduced secretion by about 80%. Acid extracts of the same tumor had produced secretin-like effects on pancreatic and biliary secretion in the dog. Since vasoactive intestinal peptide has been isolated from WDHA tumors, the hormone or hormones present in the tumors may not be identical to those normally present. Effects of a WDHA extract on gastric motility, the 4th physiologic action of secretin, were not determined.

8845 IMMUNITY TO EXPERIMENTAL CHOLERA. I. PROTECTIVE EFFECT OF HUMORAL IgG ANTITOXIN DEMONSTRATED TO PASSIVE IMMUNIZATION.

(E.) Pierce, N. F.; Reynolds, H. V. (Baltimore City Hosp., Md.). *J. Immunol.* 113(3):1017-1023, 1974.

The protective role of serum immunoglobulin G (IgG) antitoxin was studied in dogs transfused i.v. with whole plasma (15 ml/kg, antitoxin titer 2700 U/ml) or purified IgG (1.3 mg/kg, antitoxin titer 18,293 U/ml) from hyper-immunized dogs. Plasma infusion in dogs with jejunal Thiry-Vella loops increased the mean serum antitoxin titer 20-fold compared with control values and afforded significant protection against intraluminal challenge with cholera toxin (100 mg). This protection was not diminished by prior washing of the jejunum with 0.85% NaCl. Recovery of heat-labile antitoxin from jejunal washings was entirely parallel to serum antitoxin activity, which peaked at 535 U/ml 1 day after the 2nd transfusion of high-titered plasma. All antitoxic activity in plasma and jejunal washings was of the IgG class. Intact dogs transfused with antitoxic serum IgG were highly protected (82%) against orogastric challenge with viable *Vibrio cholerae* and had a mean serum antitoxin titer 30-fold greater than in controls. These results indicate that serum IgG plays a protective role at the surface of the gut mucosa or within its lumen. An appreciable proportion of serum-derived antibody appears intimately associated with the mucosal surface, where it may be protected from rapid destruction by proteolytic enzymes.

8846 ELECTRON MICROSCOPIC STUDY ON T MUCOSA IN HUMAN CHOLERA.

H.; Tsuchiya, M.; W
A.; Morishita, T.; Eukumi, H.; Ohashi, M.; Castr, A.;
Uylanogc, C. (Sch. Med., Keio Univ., Tokyo, Japan).
Gut 15(7):531-544, 1974.

Small intestinal mucosa obtained from 6 fasting pa
tients with cholera (4 men and 2 women, aged 24-46 yr)
by a p.o. biopsy technique was studied with the elec-
tron microscope. The cultures of the
were all positive for *Vibrio cholerae*.
sorptive cells, large pseudopod-like cytoplasm
processes with deformed microvilli or without
villi (blebs) projected into the intestinal lumen
from the apical cell surface, interrupting the micro-
villous border. In the intestinal crypt, many undif-
ferentiated cells possessed pseudopod-like cytoplasmi
projections that extended into the crypt lumen. The
swelling of mitchondria, disappearance of mitochon-
drial cristae, an increase in the number of vesicles
of the Golgi apparatus, and dilation and vesiculation
of endoplasmic reticulum were observed in the epithe-
lial cells. The apical portion of epithelial
at the base of villi was edematous. Cytoplasm
fragments enclosed by a plasma membrane, desq
epithelial cells, cytoplasmic organelles, and
tory granules were lying free in the intestinal lum
Marked irregular widening of the interepithelial
spaces in the jejunal mucosa was apparent at the mid-
villous area. There were many cystic vacuoles in
the epithelial cytoplasm which contained abundant
fluid. Whether these vacuoles indicate de
epithelial changes, transport of fluids in
plasm, or accumulation of some substance p
endoplasmic reticulum is not known. The re
gest that the degree of cholera diarrhea depen
the severity of the epithelial changes and the
ber of epithelial cells with cytoplasmi

8847 CALCIUM-BINDING PROTEIN AND VIT METABOLISM IN EXPERIMENTAL PROT TRITION.

(E.) Kalk, W. J.; Pimstone, B.
Cape Town Med. Sch., South Africa). *B*
(3):569-578, 1974.

Intestinal and renal vitamin D-dependent
binding protein (CaBP) activity and vitam
olism were investigated in protein-def
rats (40 g/kg/day casein diet) and in
mals (200 g/kg/day casein diet).
weeks intestinal CaBP activity of
protein diet was 70.7 ± 3.4% of the contr
renal CaBP activity was not significantly

spond to pharmcological doses of vitamin D
rate of conversion of ^{3}H-vitamin D_3 (540
to 25 hydroxycholecalciferol (25-HCC) and
ance rates of plasma 25-HCC were similar i

deficient and protein-sufficient rats. Hydroxylation of vitamin D_3 to 25-HCC occurs in the liver and was almost complete 2 hr after injection of labeled vitamin D_3 in both groups. Similarly, the rapid disappearance of 25-HCC from the plasma of protein-deficient and control animals suggests that renal hydroxylation of vitamin D_3 is normal in protein-deficient animals. In these animals reduced CaBP is probably a result of reduced CaBP synthesis as a consequence of deficient amino acid substrate, rather than hepatic or renal abnormalities in vitamin D_3 metabolism.

8848 ARTHRITIS AND INTESTINAL DISEASES: A COMPARISON OF TWO FAMILY STUDIES.

(E.) Haslock, I.; Macrae, I. F.; Wright, V. (Gen. Infirm., Leeds, England). *Rheumatol. Rehabil.* 13(3):135-140, 1974.

In a survey of the musculoskeletal complications of ulcerative colitis and Crohn's disease, 91 patients with ulcerative colitis, 116 patients with Crohn's disease, and 449 of their relatives and spouses were examined clinically and radiologically. A further 96 relatives and spouses were reviewed radiologically only. Intestinal synovitis was diagnosed in 11 probands with ulcerative colitis and 24 with Crohn's disease. The pattern of joint involvement was similar in the 2 family studies, with large joints predominating over small limbs and lower-limb joints over upper limbs. In both series the knee was most commonly affected. Sacro-iliitis was found in similar proportions of probands, first-degree relatives, second-degree relatives, and spouses in each study. More of the subjects in the ulcerative colitis group were diagnosed as having ankylosing spondylitis, while a greater proportion of subjects with sacroiliitis in the Crohn's disease study were female. It is possible that the lower incidence of definite ankylosing spondylitis in the Crohn's study reflected an increased effort in rejecting back pain which was felt to be insignificant.

8849 REACTION OF HUMAN SMALL INTESTINE TO AN INTRALUMINAL TUBE AND ITS IMPORTANCE IN JEJUNAL PERFUSION STUDES.

(E.) Cook, G. C.; Carruthers, R. H. (Dept. Med., Univ. Zambia, Lusaka). *Gut* 15(7):545-548, 1974.

A double-lumen tube with a mercury weight attached to its distal end was positioned in the small intestine of 6 subjects (4 men and 2 women, aged 25-44 yr) prior to elective laparatomy. Clinical diagnosis of the patients was left ureteric calculus (1); carcinoma of urinary bladder, and *Schistosoma haematibium* infestation (2), duodenal ulcer (2), and no abnormality (1). Marked "concertinaing", or gathering of the small intestine proximal to the mercury weight, was seen at laparotomy in all 6 subjects. The ratio between the mean intestinal length from the mercury weight to the ligament of Treitz after removal of the tube to that with the tube *in situ* was 3.0 (2:5-3:8). Mean total jejuno-ileal length was 421 (320-521) cm. In 5 subjects the distal end of the tube was more than half way between the ligament of Treitz and the ileocecal valve although it was only 100-120 (mean 108) cm from the incisor teeth. The data indicate that segmental perfusion studies of the human jejunum involve a much longer length of small intestine than is generally assumed. Such studies assess absorption rates over a substantial proportion of the small intestine and are not confined to a short (30 cm) segment of the proximal jejunum. Therefore, the nutritional importance of absorption studies of amino acids, peptides, and carbohydrates is increased. Studies to measure absorption rates from the ileum should be treated with caution as part or all of the perfusion segment may be past the ileo-cecal valve.

8850 INCIDENCE AND SIGNIFICANCE OF FAECAL HYDROXYSTEARIC ACID IN ALIMENTARY DISEASE.

(E.) Wiggins, H. S.; Pearson, J. R.; Walker, J. G.; Russell, R. I., Kellock, T. D. (Central Middlesex Hosp., London, England). *Gut* 15(8):614-621, 1974.

Three-day fecal collections were obtained from 87 patients with a variety of gastroenterological diagnoses and 12 controls while consuming normal diets. Fecal weight, total fatty acids, and the proportion of hydroxystearic acid (OHSA) were measured. All patients had some easily detectable OHSA. In general, the percentage of OHSA increased with increasing fecal output; thus most patients excreting less than 20 g/day fat had less than 5% OHSA, while those with greater steatorrhea had levels of 6-23%. This trend was true for patients with chronic pancreatitis, diffuse small intestinal mucosal disease, partial gastrectomy, irritable bowel syndrome, and most of 16 patients with miscellaneous diagnoses. Exceptions were patients with mild steatorrhea with ileal disease, ileal resections without colonic resection, or bacterial colonization, all of whom had more than 5% OHSA. Patients with ileal resections who had undergone removal of most of the colon had normal OHSA levels, indicating that the colon is the main site of OHSA formation in ileal resection patients. Whether OHSA has a specific cathartic action could not be determined since the data implicate total fatty acids to the same extent.

8851 DETECTION AND LOCALIZATION OF AN OCCULT VESICOENTERIC FISTULA.

(E.) Prokop, E. K.; Buddemeyer, E. U.; Strauss, H. W.; Wagner, Jr., H. N. (Johns Hopkins Med. Inst., Baltimore, Md.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 21(4):811-818, 1974.

Detection and localization of an enterovesicular fistula in a 43-yr-old woman with a 14-yr history of chronic inflammatory bowel disease and recurrent urinary tract infection was accomplished by following a bolus of p.o. ^{198}Au-colloid (100 μc) as it tranversed the gastrointestinal tract with serial scintiphotos and simultaneously monitoring the urine. The ^{198}Au appeared in the urine between the image taken at 1 hr and 30 min and 1 hr and 45 min, suggesting that the fistula was located in the area involving the terminal ileum and ascending colon. To confirm the site of the fistula, a mixture of barium and tracer (50 μC) was administered rectally. The tracer did not appear in the urine until the barium reached the area of the cecum. Laparotomy showed that the cecum was adherent to the bladder, but no fistula was demonstrable by methylene blue instillation into the bladder. Postoperatively, the urinary tract infection cleared, and reexamination with p.o. ^{198}Au-colloid revealed no activity in the urine. The radiation dose to the gonads in this procedure is 42 mrads. The procedure is safe, simple to perform, and well tolerated.

8890 ORIGIN OF CIRCULATING ANTIGEN FROM THE SCHISTOSOME GUT. AN IMMUNOFLUORESCENT STUDY. *(E.)* Lichtenberg, F. v.; Bawden, M. P.; Shealey, S. H. (Harvard Med. Sch., Boston, Mass.). *Am. J. Trop. Med. Hyg.* 23(6):1088-1091, 1974.

Adult *Schistosoma mansoni* males and females were obtained intact from 10-week infected Swiss white mice by portal perfusion and subjected to immunofluorescent staining with specific anti-circulating schistosome antigen (CSA) rabbit immunoglobulin plus goat anti-rabbit immunoglobulin-fluorescein conjugate. Worm sections layered with specific rabbit-anti-CSA antiglobulin reproducibly showed bright apple-green staining at all levels of the gut examined, i.e., esophagus as well as ceca. Specific fluorescence was distinct from the orange to chartreuse antifluorescence of vitellaria granules, and appeared somewhat uneven, just short of particulate. It was intense but spotty in the gut lumen and at its epithelial surface, it extended somewhat more faintly through the epithelial syncytium to its base with a sharp cutoff at the presumed level of the basement membrane. The worm tegument and parenchyma were negative. Worm sections layered with wide-spectrum mouse antiglobulin showed diffuse apple-green fluorescence throughout, most prominent in the tegument. Eggs in liver tissue remained unstained by specific anti-CSA antiglobulin, but showed the familiar bright staining of miracidia, and their envelopes, when broad-spectrum mouse antiglobulin was used. These results support the finding that CSA originates in the schistosome gut, and not in the integument. The CSA localization described does not result from a nonspecific affinity for rabbit globulins, but must be considered specific. It is suggested that the timing of the appearance of CSA (18 days) could be related to differentiation of the gut as it passes from the schistosomulum to the adult stage.

8891 TWO-YEAR FOLLOW-UP ON HYCANTHONE-TREATED Schistosomiasis mansoni PATIENTS IN ST. LUCIA. *(E.)* Cook, J. A.; Woodstock, L.; Jordan, P. (Ministry Health, Castries, St. Lucia, West Indies). *Am. J. Trop. Med. Hyg.* 23(5):910-914, 1974.

Of 433 *Schistosomiasis mansoni* patients who were treated with hycanthone (3 mg/kg i.m.), 190 were seen 2 yr after treatment and 143 of these also had follow-up examinations at 6 weeks, 6 months, and 1 yr. Visible eggs were not detected in 86% at 1 yr nor in 76% at 2 yr. The reinfection rate, as judged by a significant increase in egg excretion, was 15% at 2 yr and was related to the geographic area to which the patient returned. Total reduction in egg excretion was 98% at 1 yr and, even with reinfections, was 87% at 2 yr. At 24 months after treatment, 36 of 39 patients (92%) with hepatomegaly showed a significant decrease (>2 cm) in liver size in either the midclavicular or midsternal lines. Of 18 patients with enlarged spleens, 15 (83%) showed a decrease in organ size of 1 grade on the Hackett scale, and 1/2 of the spleens were no longer palpable. Eighteen of the patients with hepatomegaly and 11 of those with splenomegaly were aged 10-14 yr. Among patients with liver enlargement, those 15 yr or older showed less clinical response than younger patients. The number of patients does not permit statistical comparison.

8892 SERUM AND INTESTINAL FLUID IMMUNOGLOBULINS IN PATIENTS WITH GIARDIASIS. *(E.)* Jones, E. G.; Brown, W. R. (Denver VA Hosp., Colo.). *Am. J. Dig. Dis.* 19(9):791-796, 1974.

To test the possibility that immunoglobulin deficiency is a factor predisposing to symptomatic giardiasis in the general population, immunoglobulins were measured in serum and intestinal fluids of 9 giardiasis patients (8 after eradication of *Giardia lamblia*) and 12 healthy controls. The concentrations of IgG, IgA, IgM, and IgE in serum from the 2 groups and of IgA and IgM in intestinal fluids were similar. However, intestinal fluid IgG levels were significantly higher in the patients (5.8 ± 6.3 mg/100 ml) than in the controls (1.1 ± 1.9 mg/100 ml). This difference is unexplained and is of uncertain biological significance. Even though *G. lamblia* infection is very common in grossly immunoglobulin-deficient patients, giardiasis in generally healthy persons is probably not etiologically related to immunoglobulin deficiencies.

GENERAL

Regional Enteritis

8910 HL-A 27 IN CROHN'S DISEASE. *(E.)* Jacoby, R. K.; Jayson, M. I. V. (Dept. Med., Univ. Bristol, England). *Ann. Rheumatol. Dis.* 33(5):422-424, 1974.

The human leukocyte antigen (HL-A) profiles of 74 patients with Crohn's disease were investigated to determine whether those with HL-A 27 were more likely to have rheumatological disease. Of the 74 patients, 6 had HL-A 27, 3 with Crohn's disease involving the large intestine; only 16 of the 68 patients without HL-A 27 had large bowel disease. Of the 74 patients, 13 experienced periods of back pain; however, neither sacroiliitis nor ankylosing spondylitis were present in any of these 13. Limb joint symptoms were noted in 2 patients and it was possible that these were episodes of the synovitis of Crohn's disease. HL-A 27 was not present in either of these 2. Three patients had limitation of movement in the lumbar spine. The restriction was in flexion, however, and degenerative changes of the spine showed no evidence of sacroiliitis. Evidence of sacroiliitis was obtained in 3 patients, the joints had completely fused in 1 and the other 2 showed typical erosive changes. No evidence of typical ankylosing spondylitis was present and none of these 3 had HL-A 27. In 3 patients studied particularly because of known Crohn's disease and typical ankylosing spondylitis, HL-A 27 was present in only 1. Thus in this series of 74 patients with Crohn's disease, sacroiliitis was found in 3 but none had ankylosing spondylitis. Perhaps it is necessary for HL-A antigen to be present before sacroiliitis can progress to typical ankylosing spondylitis. This antigen may be useful as a genetic marker to indicate those who are susceptible to the progression of sacroiliitis to spinal involvement. The frequency of HL-A 9 was also determined and was on the same order as that found in a control population.

8911 SHORT BOWEL SYNDROME FOLLOWING RESECTION FOR CROHN'S DISEASE. *(E.)* Kristensen, M.; Lenz, K.; Nielsen, O. V.; Jarnum, S. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(6): 559-565, 1974.

Malabsorption and disability were evaluated in 28 patients (13 males and 15 females, aged 17-67 yr) who had undergone surgery for Crohn's disease. The patients was subjected to extensive intestinal resection (75 to 270 cm of small intestine) at various levels: distal ileum (17 cases, in 5 of whom an ileostomy was also performed); total ileum resection (5); jejunum plus ileum (3); and jejunum (3). In addition, a rightsided hemicolectomy was performed in 9 patients and total proctocolectomy in 1. Absorption studies were performed on the 24 patients who had not suffered recurrence at the time of the study. Steatorrhea in patients with distal ileal resection plus ileostomy (averaging 266 mM/24 hr) far exceeded that of the other groups. Abnormal bacterial growth and disturbed bile acid metabolism did not fully account for this finding. Abnormal bacterial growth was present in all 3 patients with jejunal resection, but was inconsistently present in the other groups. External pancreatic function was slightly depressed in 1/3 of the total case material. Working capacity was retained in half the patients. Two-thirds were underweight. Only 3 patients were incapacitated by diarrhea. It was concluded that an active surgical attitude to radical intestinal resection is justified in patients with extensive Crohn's disease which does not respond satisfactorily to medical treatment.

8912 PERIPHERAL BLOOD T AND B CELLS IN CHRONIC INFLAMMATORY BOWEL DISEASE. *(E.)* Strickland, R. G.; Korsmeyer, S.; Soltis, R. D.; Wilson, I. D.; Williams, Jr., R. C. (Univ. New Mexico Sch. Med., Albuquerque). *Gastroenterology* 67(4):569-577, 1974.

Proportions and absolute numbers of peripheral blood thymus-derived (T) and bone marrow-derived (B) cells were measured in 58 patients with Crohn's disease (aged 14-72 yr), and in 18 patients with chronic ulcerative colitis (aged 22-70 yr), and compared with a control population of 64 individuals. T cell proportions and numbers were significantly decreased in Crohn's disease. In chronic ulcerative colitis, T cell proportions were normal and decreased T cell numbers were related to a significantly lower than normal total peripheral blood lymphocyte count. Proportions and absolute numbers of B cells bearing surface immunoglobulin A or M were significantly increased in both Crohn's disease and chronic ulcerative colitis. The alterations in T and B cells were unrelated to disease activity, site, or duration or mode of treatment. These studies indicate that the cellular immune system may be abnormal in Crohn's disease and may be related to a quantitative defect in T cells. A deficit of peripheral blood T cells may be due to either decreased production, increased loss from the gastrointestinal tract, or sequestration in the bowel itself. These findings further emphasize the importance of peripheral blood lymphocyte abnormalities in inflammatory bowel disease.

8913 SERUM LYMPHOCYTOTOXIC AND LYMPHOCYTOPHILIC ANTIBODY ACTIVITY IN INFLAMMATORY BOWEL DISEASE. *(E.)* Korsmeyer, S.; Strickland, R. G.; Wilson, I. D.; Williams, Jr., R. C. (Univ. New Mexico Sch. Med., Albuquerque). *Gastroenterology* 67(4): 578-583, 1974.

Lymphocytotoxic activity was detected in 10 of 58 sera from patients with Crohn's disease and in 2 of 18 sera obtained from subjects with chronic ulcerative colitis. These lymphocytotoxic sera showed no clearcut human leukocyte antigen specificity and were considerably more cytotoxic for normal lymphocytes than for those obtained from Crohn's disease or chronic ulcerative colitis. No apparent relationship could be established between the presence of lymphocytotoxic activity in individual sera and the proportions or absolute numbers of peripheral blood T or B lymphocytes, or in the clinical activity of disease. Three sera from patients with Crohn's disease showed striking lymphocytophilic activity increasing 2- to 7-fold the proportions of normal peripheral blood lymphocytes bearing surface immunoglobulin (Ig) when incubated in their presence. The increment in surface Ig was shown to be principally in cell-adsorbed IgG. Two of these sera showed high degrees of lymphocytotoxic antibody as well. Two also had low absolute numbers of T lymphocytes. None of the 18 chronic ulcerative colitis patients demonstrated Ig which would bind onto normal lymphocytes.

8914 URINARY EXCRETION OF OXALATE, CALCIUM, MAGNESIUM, AND URIC ACID IN INFLAMMATORY BOWEL DISEASE. RELATIONSHIP TO UROLITHIASIS. *(E.)* Farmer, R. G.; Mir-Madulessi, S. H.; Kiser, W. S. (Cleveland Clin., Ohio). *Cleve. Clin. Q.* 41(3): 109-118, 1974.

Urinary excretion of oxalate, calcium, magnesium and uric acid was measured in 80 patients with Crohn's disease (42 men and 38 women, mean age 36.5 yr), 18 with ulcerative colitis (10 men and 8 women, mean age 41.5 yr) and 27 controls. Patients with ulcerative colitis had less urinary magnesium excretion and more calciuria than controls. Of the 80 Crohn's disease patients, 51 had ileocolic disease, 15 had disease of the small intestine, and 14 had colonic disease. Patients with ileocolic disease had significantly lower urinary calcium, magnesium, and oxalate. Those with small intestine disease had lower urinary magnesium and higher oxalate excretion when compared with patients having colonic disease, ulcerative colitis, or controls. Urinary oxalate levels reached maximum levels in patients who had ileal disease and had undergone ileal resection. Of the 98 patients with inflammatory bowel disease, 51 underwent 61 operations. Patients with ileal resection had less urinary magnesium and more urinary oxalate. Patients with ileal bypass had significantly less urinary calcium, uric acid, and magnesium values. Those with ileostomy and ileorectal anastomosis had less urinary magnesium excretion. Nine patients (6 women and 3 men, mean age 41 yr, 11%) had urolithiasis. All 9 had longstanding ileal Crohn's disease (mean 18 yr), 8 had operations, 5 had ileal resections. All but 1 had calcium stones. One, who had previously undergone ileostomy, had uric acid stones. In these 9 patients, urinary oxalate was increased and magnesium and calcium values were decreased. It was concluded that of patients with inflammatory bowel disease, those most likely to develop renal calculi have had Crohn's disease involving the ileum for a long period of time.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

8924 ENDOCRINE-LIKE CELLS IN RAT STOMACH: EFFECTS OF 6-HYDROXYDOPA ON AMINE STORES AND AMINO ACID DECARBOXYLASE ACTIVITIES. A CHEMICAL, FLUORESCENCE HISTOCHEMICAL AND ELECTRON MICROSCOPIC STUDY. *(E.)* Hakanson, R.; Larsson, L. I.; Sundler, F. (Dept. Pharmacol., Univ. Lund, Sweden). *J. Pharmacol. Exp. Ther.* 191(1):92-101, 1974.

The mucosa of the oxyntic gland area in the rat stomach contains 2 types of endocrine-like cells belonging to an enterochromaffin-like cell system. Both cell types produce and store histamine and, if supplied with dopa, are capable of producing and storing dopamine. Treatment of male Wistar rats with 6-hydroxydopa (100 mg/kg i.p.) for 3 days caused a 10-fold increase in oxyntic histidine decarboxylase activity, without affecting histamine concentration, and more than doubled pyloric dopa decarboxylase activity. At the same time, 6-hydroxydopa treatment significantly reduced the amount of dopamine appearing in the enterochromaffin-like cells after injection of L-dopa (100 mg/kg i.p.). Electron microscopic examination of the 2 types of endocrine-like cells revealed markedly swollen granules in cells with vesicular-type granules, but no damage in cells with uniform granules. 6-Hydroxydopamine (100 mg/kg i.p.) did not produce ultrastructural changes in either type of cell. It is suggested that the enzyme-activating effect of 6-hydroxydopa is secondary to the granular damage, which in turn impairs the dopamine-storing, but not the dopamine-forming, capacity of the cells.

8925 HISTOCHEMICAL PROPERTIES OF THE ANTRAL GASTRIN CELL. *(E.)* Larsson, L. I.; Sundler, F.; Hakanson, R.; Grimelius, L.; Rehfeld, J. F.; Stadil, F. (Dept. Histol., Univ. Lund, Sweden). *J. Histochem. Cytochem.* 22(6):419-427, 1974.

The antropyloric mucosa of rat, rabbit, cat, pig, and man was investigated using certain modifications of the original Falck-Hillarp procedure (exposure of freeze-dried sections to formaldehyde gas). In rabbit, cat, pig, and man, combined formaldehyde-ozone treatment induced intense fluorescence in a large number of epithelial cells when examined under a fluorescence microscope. By subsequent treatment of the sections for immunohistochemical detection of gastrin (immunofluorescence or immunoperoxidase labeling), it could be shown that these cells were identical with the gastrin cells. The gastrin cells of cat and man could be visualized also by treatment with formaldehyde-HCl, a feature not shared with the gastrin cells of rabbit and pig. The gastrin cells in the rat antrum gave no fluorescence with either formaldehyde-ozone or formaldehyde-HCl. From histochemical model experiments and cytospectrofluorometric analyses it appears probable that the formaldehyde-ozone-induced fluorescence reflects the presence of a peptide with NH_2-terminal tryptophan. The chemical background of the fluorescence induced by formaldehyde-HCl treatment is as yet obscure. The gastrin cells of all animals studied stained with silver in the Grimelius method. Argentaffin and diazo staining as well as silver staining according to Hellerström and Hellman were carried out on sections from human antrum only. The gastrin cells were negative with these stains, but they stained with lead-hematoxylin. These properties support the view that the gastrin cells are identical with the so-called G cells.

8926 MECONIUM CORPUSCLES IN INTESTINAL EPITHELIUM OF FETAL AND NEWBORN PRIMATES. *(E.)* Ruebner, B. H.; Kanayama, R.; Bronson, R. T.; Blumenthal, S. (Sch. Med., Univ. California, Davis). *Arch. Pathol.* 98(6):396-399, 1974.

The small intestinal epithelium of fetal (1 rhesus and 2 bonnet) and newborn monkeys (19 rhesus, 11 bonnet, 6 stumptailed macaques, 5 Indian langurs, 2 sooty mangabeys, and 1 Guinea baboon) and 7 human embryos, fetuses, and neonates, all contained pigmented granules (meconium corpuscles) as demonstrated by histochemistry and light and electron microscopy. Light microscopy revealed pigmented granules in the epithelial cells of the villi tips. These were irregularly spherical, yellowish-green, and measured up to approximately 5 μ in diameter. The inclusions were also found in the lamina propria in monkeys at the tips of the villi and tended to be larger (up to 10 μ in diameter). In the youngest specimens, the pigment was predominantly epithelial while in the mature infants the pigment in the lamina propria was more pronounced. The oldest infant monkey in which the pigment was found was 14 days old. Electron microscopy showed the pigment finely granular and membrane-bound. There were no histochemical reactions for bilirubin or hemosiderin; there was, however, a positive reaction for tetrapyrrol. It was suggested, therefore, that the major part of the pigment is composed of a tetrapyrrol related to, but not identical with, bilirubin. It was also postulated that the pigment of the meconium bodies is derived from the meconium and transferred into the vascular and lymphatic circulations, possibly *via* the intercellular spaces, where some granular dense material, possibly pigment, was seen (rarely) by electron microscopy.

8946 INTESTINAL ABSORPTION OF INTAKE ANTIGENIC PROTEIN.

(E.) Warshaw, A. L.; Walker, W. A. (Massachusetts Gen. Hosp., Boston). *Surgery* 76 (3):495-499, 1974.

Experiments were conducted to determine if the appearance of protein in the mesenteric lymph reflects direct and independent transport into the intestinal lymphatics or only a recirculation of protein from the portal blood. ^{3}H-Bovine serum albumin (50 mg/kg) was injected into the duodenal lumens of 6 Charles River rats prepared with cannulas in the intestinal lymphatic and portal veins. Sequential samples of portal blood and intestinal lymph were collected over a 3-hr period and assayed for ^{3}H-bovine serum albumin. Transmission of the triated bovine serum albumin into intestinal lymph and portal blood occurred regularly within the first 30 min after instillation of the labeled protein into the duodenum, with 0.76% of the administered dose appearing in the lymph and 1.11% appearing in the bloodstream during the 3-hour period. Specific activity of the intestinal lymph was unrelated to the specific activity of portal plasma over the course of the experiments, and the amount of absorption of protein into the lymph appeared to be independent of the amount absorbed into the portal blood, suggesting separate routes of absorption. The relative fractions of triated protein transmitted into the lymph *versus* the blood were unpredictable, ranging between 9-65% into the lymph. The results show that intact albumin is transported independently into both intestinal lymphatics and portal blood in the rat. This observation may help to explain the pathogenesis of numerous intestinal and systemic immune states and may be used in further studies investigating the role of local intestinal antibodies in controlling soluble antigen absorption from the small intestine.

8947 DIFFERENT EFFECTS OF HORMONAL PEPTIDES AND CYCLIC ADENOSINE 3',5'-MONOPHOSPHATE ON COLONIC TRANSPORT IN VITRO.

(E.) Yau, W. M.; Makhlouf, G. M. (Med. Coll. Virginia, Richmond). *Gastroenterology* 67(4):662-667, 1974.

The effect of various peptide hormones and other small intestinal secretory stimulants on ion and water transport by ascending and descending unfasted male albino rat colon was investigated *in vitro* with muscle-stripped everted open sac preparations. Net water flux was measured gravimetrically at 30 min intervals for 150 min, with each sac serving as its own control. Water flux rate was constant over the entire period and equal in ascending (15.6 ± 1.1 μl/hr/mg dry weight) and descending (14.9 ± 1.1) colon. Both segments responded identically to all test substances. Neither glucagon (10^{-5} M) nor pentagastrin (10^{-5} M), singly or in combination, had a significant effect on net water flux. In contrast, theophylline (10^{-5} M) and dibutyryl cyclic AMP (10^{-3} M) reduced net influx by 23% and 38%, resp. The greatest reduction was observed with ricinoleic acid (2 X 10^{-3} M) applied to the mucosal side. Changes in ionic concentration in the serosal compartment (inside the sac) at the close of the experiment and following the addition of hormonal peptides were similar to the pattern observed at the close of an initial control 60-min period. Sodium and chloride concentrations and osmolalities increased and bicarbonate concentrations decreased in both ascending and descending colon. Potassium concentration decreased in ascending and increased in the descending colon. The addition of theophylline or cyclic AMP resulted in lesser increases in serosal sodium concentration and osmolality and a greater decrease in serosal bicarbonate concentration as compared to that observed after the addition of hormonal peptides. The effects of theophylline and cyclic AMP paralleled their effect on ileal transport in other species, while the effects of hormonal peptides did not. The latter appeared to be a true species difference and was probably unrelated to the insensitivity of the distal gut to secretory stimulants.

8948 SOLUBILIZED RECEPTOR FOR INTRINSIC FACTOR-VITAMIN B_{12} COMPLEX FROM GUINEA PIG INTESTINAL MUCOSA.

(E.) Katz, M.; Cooper, B. A. (Roy. Victoria Hosp., Montreal, Canada). *J. Clin. Invest.* 54(3):733-739, 1974.

A factor that binds intrinsic factor-vitamin B_{12} complex (IF-B_{12}) was solubilized from guinea pig ileum with Triton X-100. The binding factor was soluble to the extent that it was not sedimented by centrifugation at 100,000 g for 1 hr and was small enough to enter the included volume of a Sepharose 4-B column. Furthermore, the ileal extract contained no microfine particles of membrane on electron microscope search. Following incubation of the extract with a mixture of gastric juice and ^{57}Co-labeled vitamin B_{12}, a portion of the radioactivity was excluded from a Sephadex G-200 column. When the same experiment was done with gastric juice from a patient with biologically inert intrinsic factor, radioactivity was not excluded from the gel, indicating failure of the abnormal IF-B_{12} to bind to the intestinal extract. These data suggested the presence of a specific binder of IF-B_{12} in the mucosal extract. The reactions of normal IF-B_{12} with the solubilized binding factor and with the membrane-bound receptor had several characteristics in common, including calcium dependence, temperature independence, and pH optimum near neutral. Extracts from the distal intestine were more active than those from the proximal. The solubilized binding factor appeared specific for IF-B_{12} in that it was not blocked by prior incubation with excesses of free vitamin B_{12} or intrinsic factor . Binding activity was decreased by incubation at pH 2.0, heating to 56 C, and incubation with chymotrypsin and dithiothreitol. Binding activity was unaffected by incubation with trypsin, neuraminidase, and sulfhydryl blockers. The solubilized receptor for IF-B_{12} appears to be a protein with function dependent on peptide and disulfide linkages.

8949 INTESTINAL ABSORPTION OF PEPTIDES. PEPTIDE UPTAKE BY SMALL INTESTINE OF Rana pipiens.

(E.) Cheeseman, C. I.; Parsons, D. S. (Dept. Biochem., Univ. Oxford, England). *Biochim. Biophys. Acta* 373 (3):523-526, 1974.

Uptake of glycyl-L-leucine in the small intestine of

Rana pipiens was studied with a vascularly perfused preparation. The transfer systems for L-leucine and glycine were completely saturated at the luminal concentration of 10 mM. Addition of 5 mM glycyl-L-leucine to a mixture of 10 mM L-leucine and glycine increased the rate of appearance of L-leucine in the vascular effluent by 85% and that of glycine by 210%. When dipeptide alone (5 mM) was present in the lumen, glycine transfer was increased 3-fold compared with that from 10 mM amino acid mixture. L-Leucine transfer was increased to a much smaller extent. Transfer of amino nitrogen from the dipeptide glycyl-L-leucine was not exclusively *via* the peptide transport system. Comparison of the total transfer of amino N from the peptide alone with the activity of the peptide transport system showed that the latter accounted for 60% of all amino N appearing in the vascular effluent when the dipeptide was present in the lumen. The remaining amino N must be handled by systems accessible to free amino acids in the lumen.

8950 USE OF INERT GASES AND CARBON MONOXIDE TO STUDY THE POSSIBLE INFLUENCE OF COUNTERCURRENT EXCHANGE ON PASSIVE ABSORPTION FROM THE SMALL BOWEL. *(E.)* Bond, J. H.; Levitt, D. G.; Levitt, M. D. (VA Hosp., Minneapolis, Minn.). *J. Clin. Invest.* 54(6):1259-1265, 1974.

To determine the influence of countercurrent exchange on passive absorption from the small intestine, absorption of CO, which is tightly bound to hemoglobin and cannot exchange, was compared with that of 4 unbound gases (H_2, He, CH_4, and ^{133}Xe) which should exchange freely. Absorption rates of the 5 gases were measured from closed loops of rabbit jejunum. The degree to which absorption of the unbound gases fell below that predicted from CO absorption was assumed to provide a quantitative estimate of countercurrent exchange. On the assumption that villus and central hemoglobin concentrations are equal, the flow that equilibrates with CO (F_{CO}) was calculated as 7.24 ml/min/100 g. Observed absorption rates of the unbound gases were 2-4 times greater than predicted by an equation assuming complete equilibration for these gases between lumen and F_{CO}. This was the opposite of what would occur if countercurrent exchange retarded absorption of the unbound gases. Further calculations were performed with a model that distinguishes between the flow and diffusive components of gas absorption in the rat intestine. The flow-limited fraction of the total uptake of unbound gases was still 1.8 times greater than predicted by CO absorption. A possible explanation for this discrepancy is that plasma skimming reduces villus blood hemoglobin to about 60% that of central blood. Thus, F_{CO} is about 1.7 times greater than initially calculated. With this correction factor, absorption of unbound gases predicted by CO measurements was comparable to the uptake of these gases by the equilibrating flow. Countercurrent exchange did not influence passive absorption under the conditions of this study.

8951 L-PHENYLALANINE INTERACTIONS WITH STRUCTURALLY RELATED SUBSTANCES AT THE INTESTINAL MUCOSA. *(E.)* Wapner, R. A.; Lifshitz, F. (North Shore Univ. Hosp., Manhasset, N.Y.). *Biochem. Med.* 11(4):370-375, 1974.

Interactions between L-phenylalanine and biochemically and physiologically related substances were investigated. L-Alanine, cycloleucine, and L-serine inhibited rat intestinal transport of 1 mM L-phenylalanine *in vivo* when simultaneously present in concentrations of 10 mM or more. β-2-Thienyl-DL-alanine was a more effective inhibitor even at 5 mM levels. L-Dihydroxyphenylalanine had no effect on absorption of 1 mM L-phenylalanine even when present in concentrations up to 20 mM. The data indicate that β-2-thienyl-DL-alanine may be a competitor for the specific translocation mechanism of L-phenylalanine, and that L-alanine, cycloleucine, and L-serine interfere with L-phenylalanine absorption across the intestine through the transport system common for neutral amino acids.

8952 INTERFERENCE OF ORAL IMMUNIZATION WITH THE INTESTINAL ABSORPTION OF HETEROLOGOUS ALBUMIN. *(E.)* Andre, C.; Lambert, R.; Bazin, H.; Heremans, J. F. (Edouard Herriot Hosp., Lyon, France). *Eur. J. Immunol.* 4(10):701-704, 1974.

Single 200 mg intragastric administrations of human serum albumin (HSA) were given to 15 female Wistar rats to test the effect of local immunization of the rat's intestine on subsequent digestive absorption of the antigen *in vivo*. The capacity of this group to absorb a similar intragastric test dose of HSA 2 weeks later was greatly impaired and reduced to 33, 25, and 60% of the mesenteric venous serum HSA values at 1, 2, and 3 hr, resp., measured in 15 unprimed animals receiving a 200 mg test dose of the antigen. Administration of 200 mg test doses of HSA mixed with intestinal scrapings from intragastrically immunized rats to 10 unprimed rats fasted for 24 hr also caused a decrease in intestinal absorption as compared to 10 controls receiving the antigen with nonimmune intestinal secretions. Mean mesenteric venous serum HSA values 2 hr after the test doses were 27.2 and 41.8 ng/ml, resp., in test animals and controls. These results indicate that preformed antigen-antibody complexes are denied absorption by the gut wall. The site of impairment of antigen uptake in actively immunized animals appears to be partly intraluminal, although binding of the antigen by antibody present in lamina propia fluid was not excluded as an additional factor. Radioimmunoassay HSA values were always much higher than HSA values determined with radial immunodiffusion, and the former method appeared to be interfered with by some material different from undegraded HSA. The radioimmunoassay-determined HSA value in intragastrically-primed rats 2 weeks later was equal to the value (140 μg/ml) measured by the same method in nonprimed animals 3 hr after administration of the antigen; this appears quite improbable and casts doubt on the validity of the procedure. Much of the inhibiting effect of local intragastric HSA priming appeared to be due to binding of the antigen by secreted antibody, probably immunoglobulin A, in the bowel lumen.

8953 DELINEATION OF THE DIMENSIONS AND PERMEABILITY CHARACTERISTICS OF THE TWO MAJOR DIFFUSION BARRIERS TO PASSIVE MUCOSAL UPTAKE IN THE RABBIT INTESTINE.

(E.) Westergaard, H.; Dietschy, J. M. (Univ. Texas Southwestern Med. Sch., Dallas). *J. Clin. Invest.* 54(3):718-732, 1974.

The rate of passive absorption into intestinal mucosal cells from circular pieces of the upper half of rabbit jejunum (10-15 cm in length) was determined for 2 major diffusion barriers: an unstirred water layer and the cell membrane. The unstirred water layer was resolved into 2 compartments: 1 behaving like a layer of water overlying the upper villi and the other probably consisting of solution between villi. The superficial layer was physiologically most important during uptake of highly permeable compounds and varied in thickness from 115-334 µm as the mixing rate of the bulk mucosal solution was varied. From data derived from a probe molecule whose uptake was limited by the unstirred layer, the effective surface area of this diffusion barrier also was determined to vary with stirring rate and equalled only 2.4 cm^2/100 mg in the unstirred condition; it increased to 11.3 cm^2/100 mg with vigorous mixing. This latter value, however, was still only 1/170th of the anatomical area of the microvillus membrane. These values were then used to correct the uptake rates of a number of passively absorbed probe molecules for unstirred layer resistance, and these data were in turn used to calculate the incremental free energy changes associated with uptake of specific substituent groups to the probe molecules. Permeability data for C_4-C_{12} fatty acids and C_6-C_8 alcohols 6:0 and 8:0 plotted as a log function of chain length for these molecules resulted in an average increase in the permeability coefficient by a factor of 1.52 for each methylene group added to the chain. This in turn equaled an incremental free energy change of -258 calories/M. Addition of hydroxyl group resulted in a free energy change of +564 calories/M for 4 bile acids, while substitution of the taurine group for the carboxyl function resulted in a free energy change of +1463 calories/M. In going from a secondary aldehyde group to a carboxylate anion, the free energy changed by +1162 calories/M. Thus, the unstirred layer in the intestine is rate-limiting for the mucosal uptake of compounds such as fatty acids and cholesterol. In addition, the lipid membrane of the microvillus surface appears to be relatively polar in structure.

8954 ELECTRON PROBE ANALYSIS OF CALCIUM TRANSPORT BY SMALL INTESTINE.

(E.) Warner, R. R.; Coleman, J. R. (Sch. Med. Dent., Univ. Rochester, N.Y.). *J. Cell Biol.* 64(1):54-74, 1975.

Calcium transport in small intestine of male Rochester rats and male White Leghorn chicks was studied at the cellular level with the electron probe x-ray microanalyzer. Tissues were examined directly after removal as well as after incubation in a calcium solution. In both preparations, discrete calcium localizations were found associated with intracellular and extracellular goblet cell mucus. The *in vitro* preparations showed ^{45}Ca in transit across the absorptive epithelium in discrete localizations. Although the primary path of transport was along lateral cell borders, some localizations were found in the cytoplasm in a supranuclear position. Vitamin D-deficient animals showed a decrease in the number of calcium localizations in transit across the epithelium, whereas animals given vitamin D_3 (500 IU p.o.) 72 hr before sacrifice had increased numbers of calcium localizations. The results suggest that calcium is transported while in a sequestered form and indicate that goblet cell mucus plays a role in this transport process.

8955 SODIUM TRANSPORT BY THE SMALL INTESTINE OF NEW-BORN AND SUCKLING PIGS.

(E.) Henriques de Jesus, C.; Smith, M. W. (Inst. Animal Physiol, Cambridge, England). *J. Physiol. (Lond.)* 243(1):211-224, 1974.

Sodium transport was measured across *in vitro* preparations of pig ileum taken at birth or during the 1st 10 days of postnatal life. Both the unidirectional and net fluxes of sodium fell shortly after colostrum was ingested by the newborn piglet. These changes were associated with falls in short-circuit current, open-circuit voltage and tissue conductance, and with the appearance of protein-filled vacuoles within the mucosal epithelium. Overnight fasting of piglets followed by a period of suckling caused all sodium fluxes to revert to values similar to those found in the newborn animal. The short-circuit current also increased on fasting but the magnitude of this effect decreased with age. The suckling-dependent inhibition of sodium transport was not associated with any change in the level of adenine nucleotides in the mucosa. However, the rate at which sodium entered the intestinal mucosa of suckled pigs was only 1/2 that of the newborn. Pinocytosis might use up or chemically modify the microvillar membrane, making it less permeable to sodium. Subsequent fasting would, by replenishment or further modification of existing membrane surface, allow the epithelium to recover its original permeability to sodium and possibly regain the ability to undergo a further cycle of pinocytotic activity.

8956 GALACTOSE FLUXES ACROSS BRUSH BORDER OF HAMSTER JEJUNAL EPITHELIUM: EFFECTS OF MUCOSAL ANAEROBIOSIS.

(E.) Baker, R. D.; Lo, C. S.; Nunn, A. S. (Univ. Texas Med. Branch, Galveston). *J. Membr. Biol.* 19(1/2):53-78, 1974.

Unidirectional influxes across the brush border membrane of everted hamster jejunum were determined by measuring rate of uptake during 0.5-1.0 min of incubation in 5 mM galactose. ^3H-inulin was used to correct for galactose in residual mucosal solution. Influx was greatly depressed by removing Na+ from or adding 10^{-4} phlorizin to the incubation medium. Influx was also greatly depressed by making the mucosal solution anaerobic during a 10-min preincubation period. The same severe inhibition of galactose influx by mucosal anaerobiosis also occurred under conditions in which the epithelial cells did not gain Na+. After taking into account the effect of the mucosal unstirred water layer, influxes could be normalized to a concentration of 1.0 mM at the membrane surface. At 1.0 mM the phlorizin-sensitive component of galactose influx was reduced an estimated 93% by 10 min of mucosal anaerobiosis. Unidirectional effluxes were estimated by subtracting steady-state downhill mucosal-to-serosal flux from influx. The ease of efflux was apparently augmented 2.8-fold by mucosal anaerobiosis. After 10 min of mucosal anaerobiosis, there was no longer any directional preference for movement of galactose across the brush border, nor did uphill transport occur even though a large Na+ gradient persisted. The results provide strong evidence against the theory that ion gradients provide the major source of energy for directional preference and uphill transport.

8957 EFFECTS OF CHOLERA TOXIN AND PHOSPHODIESTERASE INHIBITORS ON FLUID TRANSPORT AND CYCLIC ADENOSINE 3',5'-MONOPHOSPHATE CONCENTRATIONS IN RABBIT GALLBLADDER. *(E.)* Mertens, R. B.; Wheeler, H. O.; Mayer, S. E. (Dept. Med., Univ. California, San Diego). *Gastroenterology* 67(5): 898-906, 1974.

The effects of cholera enterotoxin on fluid transport and on mucosal cyclic AMP content were investigated in the rabbit gallbladder. Gallbladders injected intraluminally with cholera toxin (0.1 or 10 μg in Krebs-bicarbonate buffer) exhibited markedly depressed rates of fluid absorption when excised 2 hr later and studied *in vitro*. The inhibition of absorption was accompanied by a significant (approximately 3.5-fold) increase in mucosal cyclic AMP content compared with control gallbladders. There was no significant difference between the effects of 0.1 or 10 μg cholera toxin on either fluid transport or cyclic AMP content, indicating that a maximum biochemical and physiological effect was achieved with the lesser dose. The presence of theophylline (10 mM) or papaverine (0.1 mM), both phosphodiesterase inhibitors, in the solutions bathing the gallbladders also depressed fluid transport rate and increased mucosal cyclic AMP content. Fluid transport was significantly reduced by exogenous cyclic AMP (3 mM), with the effect more pronounced in the 2nd hr of study than in the 1st. Transport rates in bladders bathed in 5'-AMP (3 mM) did not differ significantly from rates observed in bladders bathed in Krebs-bicarbonate buffer alone. The transmural electrical potential difference in the rabbit gallbladder was close to 0 and was unaffected by exposure to theophylline or papaverine.

8958 PROTEIN AND GLUCOSE-INDUCED CHANGES IN SODIUM TRANSPORT ACROSS THE PIG SMALL INTESTINE. *(E.)* Henriques de Jesus, C.; Smith, M. W. (Inst. Animal Physiol., Cambridge, England). *J. Physiol. (Lond.)* 243(1):225-242, 1974.

The effect of glucose and bovine γ-globulin on short-circuit current and sodium transport was measured across newborn and suckled pig ileum. Glucose increased the short-circuit current with an apparent K_m of 1.9 and 19.5 mM for newborn and suckled intestines, resp. The V_{max} was about 80 $\mu A/cm^2$ in each case. Bovine γ-globulin (1% w/v) applied to newborn pig ileum increased sodium chloride influx by an average of 15% but did not change short-circuit current. Tissue conductance was also greater in the presence of globulin. These effects were not seen in ileum from suckled pigs. *p*-Chloromercuriphenyl sulfonic acid (PCMPS, 0.1 mM) inhibited the globulin-induced increase in sodium influx in newborn pig ileum without changing the measured short-circuit-current. PCMPS also changed the characteristics of the glucose-dependent increase in short-circuit current, so that this response came to resemble that in ileum from suckled pigs. Dithioerythritol (50 mM) reversed this effect of PCMPS. The suckling-dependent difference in results is attributed to changes in microvillar function taking place as a consequence of long-term pinocytosis *in vivo*. The ability of PCMPS to simulate some of these changes suggests that sulfhydryl groups might be important regulators of microvillar membrane stability.

8959 INTESTINAL ABSORPTION OF HEMOGLOBIN IRON-HEME CLEAVAGE BY MUCOSAL HEME OXYGENASE. *(E.)* Raffin, S. B.; Woo, C. H.; Roost, K. T.; Price, D. C.; Schmid, R. (Univ. California Sch. Med., San Francisco). *J. Clin. Invest.* 54(6):1344-1352, 1974.

Microsomes prepared from small intestinal mucosa of male Sprague-Dawley rats contain enzymatic activity similar to that of heme oxygenase in liver and spleen. The intestinal enzyme requires NADPH, is completely inhibited by 50% CO, and produced bilirubin IX-α, identified spectrophotometrically and chromatographically. Moreover, the duodenal heme oxygenase released inorganic ^{55}Fe from ^{55}Fe-heme. Enzyme activity was highest in the duodenum where hemoglobin iron absorption is reported to be most active. In iron-deficient rats, duodenal heme oxygenase activity and hemoglobin-iron absorption rose to a comparable extent. After parenteral iron repletion of iron-deficient rats, duodenal heme oxygenase activity returned to normal. In contrast to heme oxygenase, duodenal xanthine oxidase activity fell sharply in iron deficiency and rose to base line following iron repletion. These findings suggest that mucosal heme oxygenase catalyzes the cleavage of heme absorbed in the intestinal mucosa and thus plays an important role in the absorption of hemoglobin iron. The mechanisms controlling this intestinal enzyme activity and the enzyme's role in overall regulation of hemoglobin-iron absorption remain to be defined.

8960 IN VIVO EFFECTS OF Clostridium perfringens ENTEROPATHOGENIC FACTORS ON THE RAT ILEUM. *(E.)* McDonel, J. L. (Lobound Lab., Univ. Notre Dame, Indiana). *Infect. Immun.* 10(5):1156-1162, 1974.

In vivo transport and morphological responses of perfused intact rat terminal ileum (15-20 cm oral from the ilealcecal junction) to active factors from crude cell-free extracts from *Clostridium perfring-*

ens and purified enterotoxin (protein) were studied. The ileal segments were perfused at a rate of 1.7 ml/min and 2000 erythemal U/ml of the crude extract were incubated in the segments for 45 min prior to the beginning of perfusion. The crude extract induced a reversal of net transport from absorption in 7 controls to secretion of water, sodium, and chloride in 7 experimental animals. Water movement after 60 min was reversed from 0.16 ± 0.18 (controls) to -0.53 ± 0.18 μl in test animals. Chloride transport was similarly altered throughout the 60 min period, being negative (serosal to mucosal) at 15, 30, and 45 min (-125.4 ± 53.5, -87.2 ± 55.8, and -109.1 ± 21.5 nM/cm/min, resp.). Sodium transport was inconsistent in controls and experimental animals, although a substantial rate of absorption at 15 and 45 min (90.4 ± 73.0 and 84.8 ± 51.6 nM/cm/min, resp.) in controls was altered significantly to a large rate of luminal accumulation (-195.8 ± 103.6 and -119.2 ± 46.0, resp.) at comparable intervals in experimental animals. Potassium and bicarbonate were not significantly affected. Glucose transport after 60 min was reduced from 35.5 ± 4.3 nM/cm/min for 9 controls to 10.2 ± 7.0 nM/cm/min in 9 experimental animals. Crude extract also caused histological damage to the villus epithelium by denuding the villus tips, thereby leaving the lamina propria exposed. Purified toxin (160-250 erythemal U/ml) caused similar transport changes, though little histological damage resulted. The activity of the crude extract appeared to be due to the presence of the protein toxin in the extract rather than other extraneous factors, though there was little or no dependence of fluid transport response upon toxin concentration.

8961 STRUCTURE-AFFINITY RELATIONSHIPS OF SUBSTRATES FOR THE NEUTRAL AMINO ACID TRANSPORT SYSTEM IN RABBIT ILEUM. *(E.)* Preston, R. L.; Schaeffer, J. F.; Curran, P. F. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Gen. Physiol.* 64(4):443-467, 1974.

The apparent affinities of various amino acids for the neutral amino acid transport system in rabbit ileum were determined by measuring the inhibition of L-methionine-^{14}C influx across the brush border of the distal ileum at methionine concentrations of 2 mM (unless otherwise noted). The apparent affinity was very low for compounds lacking an α-amino group, compounds with the α-hydrogen substituted by a methyl group, D-compounds, compounds with tertiary branching in the side chain, compounds with either a positive or negative charge in the side chain, and in most cases compounds with a hydrophilic moiety in the side chain. D-Methionine had an apparent affinity approximately 50-fold lower than L-methionine, indicating substantial preference for the L-isomer. High apparent affinities were exhibited by compounds with unbranched carbon or carbon-sulfur side chains. Amino acids with straight side chains such as norleucine and norvaline had affinities 2-2.5 times greater than the corresponding compounds with branched side chains (leucine, isoleucine, and valine). The branched compounds exhibited affinities which correlated with binding of only the linear portion of the side chain. The calculated change in free energy of binding was 370 calories/M/methylene group, suggesting that the binding region for the side chain is partially hydrophobic. Affinities of families of analogues (derivatives of cysteine, methionine, serine, alanine, valine, and phenylalanine) correlated with their calculated octanol/water partition coefficients and also with apparent structural and electronic differences between families. The neutral amino acid transport site appears to contain a region for binding the α-amino group, α-carboxyl group, and side chain. The regions about the α-amino group and α-hydrogen appear to be sterically limited. The side chain binding region is hydrophobic in nature and appears to be shallow, binding only the linear portion of branched or ring compounds.

8962 EFFECT OF EXCESS L-HISTIDINE DIET ON ACCUMULATION OF L-HISTIDINE IN ISOLATED RAT SMALL INTESTINE. *(E.)* Nakamura, Y.; Yosumoto, K.; Mitsuda, H. (Dept. Food Sci. Technol., Fac. Agr., Kyoto Univ., Japan). *J. Nutr. Sci. Vitaminol.* 20(2): 133-142, 1974.

The effects of protein deprivation and excessive administration of L-histidine on *in vitro* accumulation of L-histidine in Wistar rat small intestine were investigated with tissue strips and rings. Compared with a 20% casein diet, a nonprotein diet and a 5% casein + 5% L-histidine diet significantly enhanced the accumulation of L.-histidine/unit wet weight of the tissue strips. Endogenous L-histidine levels in the intestine of animals fed the excess L-histidine diet were much larger than in animals fed 20% casein and nonprotein diets. (0.709 *versus* 0.087 and 0.097 μM/g). Net accumulation/unit weight of the strips, calculated by taking into account the endogenous L-histidine levels, was still significantly higher for rats fed nonprotein and excess L-histidine diets. However, accumulations expressed in terms of the whole animal were identical irrespective of the dietary regimens. Also, intestinal rings from rats on different dietary regimens did not show the significant differences noted with the intestinal strips. Dietary conditions may affect intestinal absorption by modifying intestinal thickness rather than influencing the mucosal function to accumulate amino acid.

8963 VALIDATION OF A CHAMBER THAT ALLOWS MEASUREMENT OF BOTH TISSUE UPTAKE RATES AND UNSTIRRED LAYER THICKNESSES IN THE INTESTINE UNDER CONDITIONS OF CONTROLLED STIRRING. *(E.)* Lukie, B. E.; Westergaard, H.; Dietschy, J. M. (Univ. Texas Health Sci. Ctr., Dallas). *Gastroenterology* 67(4): 652-661, 1974.

An incubation chamber allowing measurement of both unstirred layer thicknesses and tissue uptake rates under identical conditions and with provision for systematically and reproducibly varying the rate of stirring is described in addition to validation studies on albino rabbit jejunum slices (10-20 cm of the proximal portion). The intestinal specimen is mounted between a circular platform and a retaining lid, with the mucosal surface of the intestine exposed to the mucosal incubation solution through an aperture in the retaining lid (1 cm in diameter). The height of tissue above the magnetic stirring bar in an incubation beaker can be varied by sliding a central cylinder upward or downward in a supporting lid. The stirring rate is varied by changing the rotation rate of the magnetic stirrer. At a stirring rate of 500 revolutions/min, the mean thickness of the diffusion barrier in rabbit jejunum was approximately 150 µm. Use of a marker of adherent mucosal fluid volume was of critical importance in obtaining reliable transport data, particularly when studying poorly permeant solutes or solutes solubilized in bile acid micelles. The presence of intestinal mucus or bile acids in the incubation solution increased the volume of the adherent mucosal fluid which was shown to represent a true increase in the volume of the extracellular incubation fluid trapped on the tissue. At least 3-6 min were required to fully equilibrate the unstirred layers with marker compounds such as dextran or inulin which were used for calculating the adherent mucosal fluid volume. Incubations of more than 10 min led to loss of solute molecules into the serosal compartment. Incubation times of 6-10 min gave the most reliable uptake rate measurements in the chamber. Active and passive transport studies with glucose and saturated fatty acids 8:0 and 10:0, resp., showed a linear glucose active uptake with respect to time for at least 10 min and linear passive uptake of octanoate for up to 8 min. Glucose active uptake displayed an apparent hyperbolic relation to glucose concentration in incubation medium in contrast to the linear passive uptake of fatty acids with respect to their concentrations.

MOTILITY

8999 EFFECT OF CHANGE OF POSITION ON THE FUNCTION OF THE CANINE LOWER ESOPHAGEAL SPHINCTER. *(E.)* Khan, T. A.; Crispin, J. S.; Lind, J. F. (Deer Lodge Hosp., Winnipeg, Canada). *Gastroenterology* 67(5):957-964, 1974.

A study was done to determine the influence of intrathoracic displacement on the function of the lower esophageal sphincter and to determine how gastroesophageal competence is restored by operations that replace the lower esophageal sphincter below the diaphragm. Sphincter function was studied manometrically and cinefluorographically in 23 dogs, under resting conditions and during abdominal compression. Vagotomy at the canine gastroesophageal junction resulted in a decrease in resting intraluminal pressure at the lower esophageal sphincter, and in the pressure response of the sphincter to abdominal compression. When the vagotomized lower esophageal sphincter was displaced into the chest, pressures decreased further and the sphincter became incompetent. Replacement of the vagotomized sphincter below the diaphragm (Allison repair) improved resting lower esophageal sphincter pressure but did not restore competence in all animals. Fundic-wrap combined with abdominal replacement of the lower esophageal sphincter (modified Belsey procedure) was most effective in restoring competence and this was associated with increases both in resting lower esophageal sphincter pressure and in the response to compression. Recovery of the sphincter response to compression was associated with downward displacement of the lower esophageal sphincter into the abdomen and elongation of the high pressure zone.

9000 CIRCADIAN RHYTHMICITY OF THE INTESTINAL TRANSIT IN RATS AND ITS DISTURBANCE THROUGH EXPERIMENTAL HYPERTHYROIDISM. *(E.)* Triantaphyllidis, H.; Bader, J. P. (Henri Mondor Hosp., Creteil, France). *Scand. J. Gastroenterol.* 9(5):487-494, 1974.

Intestinal transit time was studied in male Wistar rats rendered hyperthyroid either by ingestion of thyroxin (40 µg of dl-T_4) in food or by injection of 200 µg of dl-T_4 3 or 4 times/week. Transit time was measured by following the appearance of radioactivity in the stools following gastric intubation of either ^{51}Cr-chloride or ^{206}Bi-subnitrate. The control euthyroid rats demonstrated a circadian rhythm with respect to transit time which was significantly shorter when markers were given at 4 p.m. than at either 10 a.m. or midnight. The rhythm was upset in hyperthroid rats with the difference in transit time for markers given at 4 p.m. and 10 a.m. only 20-25% rather than 50% as in the controls. Although the total weight of feces eliminated was about the same for hyperthyroid as for control rats, the pattern of elimination differed significantly. Control rats eliminated most frequently between 6 p.m. and 7 a.m. with almost no elimination between 10 a.m. and 5 p.m., while hyperthyroid rats showed no such diurnal pattern.

9001 A STUDY OF PACE-MAKER ACTIVITY IN INTESTINAL SMOOTH MUSCLE. *(E.)* Connor, J. A.; Prosser, C. L.; Weems, W. A. (Dept. Physiol. Biophys., Univ. Illinois, Urbana). *J. Physiol. (Lond.)* 240:671-701, 1974.

Electrical activity of longitudinal muscle from cat duodenum was recorded in the double sucrose gap. Approximately 20% of the preparations demonstrated spontaneous slow waves; this activity, although quite uniform in a given preparation, showed considerable inter-preparation variation with respect to amplitude, frequency, and wave-form. Application of a steady hyperpolarizing current decreased slow-wave frequency and increased slow-wave amplitude while depolarizing currents increased frequency and decreased amplitude. In some quiescent preparations, membrane hyperpolarization induced slow waves 10-40 mV. Step or ramp depolarization of the membrane from hyperpolarized levels triggered slow waves in some preparations. Conductance changes during the course of a slow wave were observed with current or voltage clamp techniques. The slow-wave amplitude and time course were simulated by applying the membrane current measured under voltage clamp to the passive membrane resistance and capacitance measured independently under current clamp. Ouabain (10^{-5}) irreversibly blocked slow waves and produced a membrane depolarization equal to or slightly greater than the slow wave crest. Removal of external potassium produced a reversible sequence of events almost identical to those following ouabain application. Replacement of 50% of the external sodium chloride with sucrose produced no changes in slow-wave activity with respect to rates of rise or fall, maximum amplitude or frequency. Sucrose replacement of all external sodium chloride eliminated slow waves after 5 min; however, activity was restored by a slight hyperpolarization. Long exposures to the modified bath abolished activity. Following a conditioning exposure to potassium-free Krebs solution, readmission of potassium at normal concentrations resulted in a mean hyperpolarization of 20.5 mV and an arrest of spontaneous slow wave activity. Pump current in sodium-loaded, nonspontaneous preparations was voltage dependent. The results indicate that an electrogenic pump is present in longitudinal muscle of cat duodenum, and that oscillations in the level of pump current produce slow waves.

9002 EFFECT OF ESOPHAGEAL MOVEMENT ON INTRALUMINAL ESOPHAGEAL PRESSURE RECORDING. *(E.)*

Dodds, W. J.; Stewart, E. T.; Hogan, W. J.; Stef, J. J.; Arndorfer, R. C. (Med. Coll. Wisconsin, Milwaukee). *Gastroenterology* 67(4):592-600, 1974.

The relative movements of the esophageal lumen and the intraesophageal manometric recording site were studied and the resulting effect on intraluminal esophageal pressure recordings was assessed in 6 cats. To this end, the esophageal body, lower esophageal sphincter and diaphragmatic hiatus, as well as the recording orifice of the manometric tube, were labeled with metal markers, and cineroentgenograms and intraluminal esophageal pressure tracings were obtained simultaneously during respiration, peristalsis and abdominal compression. Esophageal movement relative to the manometric recording tips occurred under all experimental conditions. Evidence exists which indicates that the human esophagus moves similarly. The lower esophageal sphincter was found to move orad on expiration and aborad on inspiration, resulting in associated changes in the pressure recording from sensors anchored in the sphincter. These pressure oscillations are synchronous with respiration and rather than representing superimposed thoracic or abdominal pressure they reflect movement of the sphincter pressure profile relative to the recording tip. The pressure inversion point under these circumstances represents the peak and either shoulder of the lower esophageal pressure distribution curve rather than the interface between abdominal and thoracic cavity pressure influences. Thus, with respect to humans, the apparent peak resting lower esophageal pressure as determined by the conventional pull-through technique cannot be measured with accuracy since the pressure oscillations obtained during pull-through represent primarily an "artifact" due to motion rather than a real change in lower esophageal sphincter pressure *per se*.

9003 DESENSITISATION AND AGONIST BINDING TO CHOLINERGIC RECEPTORS IN INTESTINAL SMOOTH MUSCLE. *(E.)*

Young, J. M. (Univ. Cambridge Med. Sch., England). *FEBS Lett.* 46(1):354-356, 1974.

The effects of various muscarinic agonists and antagonists on the binding of ^{3}H-labeled propylbenzilylcholine mustard (^{3}H-PrBCM) to guinea pig small intestinal longitidinal muscle were studied *in vitro*. Preincubation of muscle strips in either agonists (acetylcholine, carbachol, hexyltrimethylammonium, (+)-acetyl-β-methacholine) or antagonists (atropine, methylatropinium, propylbenzilylcholine) produced an 85% inhibition in ^{3}H-PrBCM binding. Unlike the antagonists, which yielded binding curves with a Hill slope of essentially 1.0 consistent with a simple mass-action equilibrium, all the agonists yielded curves with mean Hill slopes of about 0.5. The fact that the shape of the inhibition curve for one of the agonists, carbachol, was not significantly altered but was shifted to the left suggested that the apparent negative cooperativity might be secondary to receptor desensitization. Recovery from desensitization, as measured by the rate of recovery of the contractile response to carbachol, was slow. Prior desensitization by higher concentrations of carbachol (10^{-4} M) led to only a small and statistically insignificant decrease in ^{3}H-PrBCM binding. The inhibition curve for carbachol, however, was steeper (Hill coefficient = 0.90-0.21) and shifted to the right suggesting that desensitization of muscarinic acetylcholine receptors in guinea pig longitudinal intestinal muscle is associated with a change in receptor conformation.

9004 A MATHEMATICAL MODEL OF THE SLOW-WAVE ELECTRICAL ACTIVITY OF THE HUMAN SMALL INTESTINE. *(E.)*

Robertson-Dunn, B.; Linkens, D. A. (Dept. Control Eng., Univ. Sheffield, England). *Med. Biol. Eng.* 12(6):750-757, 1974.

A mathematical model has been developed, using available data from human and dog experiments, for slow-wave electrical activity in human and dog small intestine. It comprises an interconnected chain of 100 Van der Pol relaxation oscillators programmed on a digital computer. The method of coupling and magnitude were chosen so that known small intestinal phenomena are reproduced. The oscillator chain shows a varying frequency gradient which agrees with the concept of a series of short frequency plateaus along the small intestine giving a stepwise gradient like that previously reported in living small intestine. The frequency plateau and time-dependent phase shifts in the upper part of the model correspond to the human duodenum. The distal oscillators did not exhibit fixed frequency plateaus, thus agreeing with data from animal experiments as well as with results from studies made on 2 sites in the terminal ileum in man. Simulation of a transection of the small intestine by cutting of the oscillator chain at a single point results in decreased impulse frequency in the oscillators below the cut as well as formation of a plateau at a frequency greater than the intrinsic frequency of the first oscillator below the cut. The oscillators with the decreased frequencies tended to have an inphase relationship.

9005 REGENERATION OF THE SMOOTH-MUSCLE CELLS, A STRUCTURAL BASIS FOR RESTORATION OF THE SLOW-POTENTIAL RHYTHM IN THE DISTAL PART OF THE STOMACH AFTER TRANSECTION. *(E.)*

Atanassova, E.; Jurukova, Z.; Zacheva, I. (Inst. Physiol., Bulgarian Acad. Sci., Sofia). *J. Physiol. (Paris)* 68(3):291-304, 1974.

Smooth muscle regeneration and restoration of muscle wall bioelectrical activity were studied in 16 male and female dogs following gastric transection with immediate end-to-end anastomosis at the level of the *incisura angularis*. Silver ball-shaped, subserously implanted electrodes were used to record bioelectrical activity from the muscle wall of the stomach above and below the anastomosis. During the first few days after surgery, a considerable decrease of the frequency of the slow potentials in the distal segment of the stomach was observed. On the other hand, the slow-potential rhythm in the proximal segment remained unchanged. On about the 5th day there appeared short periods of acceleration of slow potentials from the stomach below the anastomosis. From the 6th to the 10th day, the accelerated rhythm of the distal segment became constant and identical to that of the proximal segment. At different periods after the surgery tissue samples were taken from the area of anastomosis for histologic examination. Evidence for regeneration of the smooth muscle cells in the longitudinal muscle layer was indicated on the 6th day by the presence of single smooth muscle cells; on the 9th day, by groups of cells; on the 12th day, by sheaves of cells; and, at the end of the first month, by solid bridges of cells passing across the anastomosis. That the regenerated cells were indeed smooth muscle cells was shown by electron-microscopic examination.

9006 NEURAL CONTROL OF THE LOWER ESOPHAGEAL SPHINCTER: INFLUENCE OF THE VAGUS NERVES.

(E.) Rattan, S.; Goyal, R. K. (Baylor Coll. Med., Houston, Tex.). *J. Clin. Invest.* 54(4):899-906, 1974.

Studies were conducted to determine the influence of vagal stimulation on the control of lower esophageal sphincter function in the opossum. Bilateral vagotomy resulted in transient sphincter hypertension, which was prevented by pretreatment with phentolamine (1 mg/kg) or atropine (30 μg/kg). Electrical stimulation of the peripheral vagi following vagotomy caused relaxation which was less marked at lower frequencies and which was not enhanced by atropine. Additional experiments showed that atropine could reverse the rise in gastric (fundic) pressure caused by vagal stimulation although it could not concomitantly enhance sphincter relaxation. Electrical stimulation of the central vagi following bilateral vagotomy caused an increase in lower esophageal sphincter pressure which was significantly antagonized by subsequent atropine or phentolamine treatment. These studies indicate that the vagi carry purely inhibitory efferents to the lower esophageal sphincter and that they also carry afferent fibers for a centrally mediated reflex lower esophageal sphincter contraction. The increased sphincter tone resulting from vagal stimulation is due to a centrally mediated reflex, the efferents of which are not vagal since the reflex sphincter contraction presisted after bilateral vagotomy.

9007 STRUCTURE-ACTIVITY RELATIONSHIP OF SOME ANALOGUES OF GASTRIN AND CHOLECYSTOKININ ON INTESTINAL SMOOTH MUSCLE OF THE GUINEA-PIG.

(E.) Vizi, E. S.; Bertaccini, G.; Impicciatore, M.; Mantovani, P.; Zseli, J.; Knoll, J. (Semmelweis Univ. Med., Budapest, Hungary). *Naunyn Schmiedebergs Arch. Pharmacol.* 284(3):233-243, 1974.

The effect of various synthetic gastrin- and cholecystokinin-like polypeptides on contraction of the longitudinal and circular muscle layer of guinea pig ileum was studied *in vitro*. Circular muscle contractions were measured by the change in intraluminal pressure and longitudinal muscle contractions were quantitated by measuring the length of shortening of the gut following electrical stimulation. All substances tested (including human gastrin I, gastrin-II-hexapeptide, cerulein, cholecystokinin or octapeptide and cholecystokinin-pancreozymin) produced an initial increase in tension of longitudinal muscle followed by contraction of the circular muscle layer with concomitant relaxation of the longitudinal layer. This pattern was inhibited by tetrodotoxin (10^{-6} M). Hexamethonium (8.2×10^{-4}M) prevented response to the polypeptides of the circular layer, suggesting that at least 1 ganglion is involved in the nervous pathway leading to the circular muscle. Studies conducted on isolated longitudinal ileal muscle layers showed that the effect of the polypeptides is dose-dependent. Structure-activity studies indicate that the presence of tyrosine-O-sulfate is important for effective interaction between the peptides and the peptide-sensitive receptors of the ganglion cells of Auerbach's plexus. Application of the polypeptides in concentrations 2-3 times their maximally effective concentrations produced tachyphylaxis.

9008 TOPICAL DIFFERENCES OF CAFFEINE ACTION ON THE SMOOTH MUSCLE CELLS OF THE GUINEA PIG ALIMENTARY CANAL.

(E.) Ito, Y.; Osa, T.; Kuriyama, H. (Fac. Dent., Kyushu Univ, Fukuoka, Japan). *Jap. J. Physiol.* 24(2):217-232, 1973.

The effects of caffeine (5 mM) on the electrical and mechanical properties of the smooth muscle of various parts of the guinea pig alimentary canal were investigated. Caffeine produced contracture in the circular muscle of the stomach and the longitudinal muscle of the ileum, jejunum, cecum (taenia coli), and rectum. In the presence of caffeine, regular contractions ceased in the stomach and taenia coli but increased in the ileum, jejunum, and rectum. Caffeine completely eliminated the generation of the tonic response and suppressed the phasic response of K-induced contracture in all regions of the alimentary canal. In the stomach caffeine reduced the amplitude of slow waves and frequency of spike discharges, without affecting membrane potential and membrane resistance. Slow wave activity of the stomach muscle was suppressed in Na-free (tris), Ca-free, and Cl-deficient (NO_2) solutions, while the frequency of the slow wave was increased in Cl-deficient (Br) solution. Caffeine produced contracture in all these solutions without any marked change of the membrane potential or resistance. Caffeine depolarized the membrane in the ileum, taenia, and rectum and enhanced spike amplitude and frequency in the ileum and rectum. Membrane resistance decreased in the taenia coli and rectum, but increased or did not change in the ileum. ATP (5mM) and theophylline (5 mM) suppressed slow wave activity in the stomach; theophylline, but not ATP, induced contracture. If caffeine mobilizes Ca ion and increases free Ca in the myoplasm, this mobilization may be closely re-

ted to the K channel in the small intestine and
e Na channel in the large intestine. From the
sults it is concluded that topical differences
ionic permeability in the alimentary canal are a
sult of Ca release from the sequestered sites.

017 BODY COMPOSITION AND UTILIZATION OF PROTEIN AND ENERGY IN GROWING RATS AT DIFFERENT DIE-
ARY PROTEIN TO ENERGY RATIOS BY USE OF PURIFIED WHOLE
GG PROTEIN. *(E.)* Tanaka, H.; Yamaguchi, M.; Kame-
aka, M. (Fac. Agric., Univ. Tokyo, Japan). *Agric.
iol. Chem.* 38(6):1113-1120, 1974.

he effect of variation in percentage of dietary pro-
ein calorie (PC) from 0-50% by the use of purified
hole egg protein on the growth, food efficiency, pro-
ein efficiency ratio (PER), body composition, and
fficiencies of protein and energy utilization was
tudied in male weanling Wistar rats. Rats were
aintained on experimental diets with graded levels
f PC% at 410 kcalories of total metabolizable energy
or 3 weeks with purified whole egg protein as the
ietary protein source. After sacrifice, the intact
iver was removed, and its composition and the compo-
ition of the carcass was determined. Body weight
ain (7.3 g/day) and PER (3.9) attained a maximum, and
ood efficiency (0.4) reached a plateau at 10 PC% in
he diet. Carcass lipid gave a blunt peak of accumu-
lation from 5-20 PC%, while liver lipid showed a high
ccumulation in the 5 PC% diet only, attaining the
evel of the fatty liver. Body protein retention
eached a plateau at 15 PC% (little different from the level at 10 PC%), while body lipid retention gave a maximum at 10 PC% showing a gradual decrease thereafter. Energy utilization was constant when expressed as the increment of body energy retention divided by the increment of metabolizable energy intake. At and above 12 or 13 PC%, the efficiency of net body protein energy retention against metabolizable energy intake was constant at about 12.5%.

9018 SECRETIN INHIBITION OF GASTRIN-STIMULATED DEOXYRIBONUCLEIC ACID SYNTHESIS. *(E.)* Johnson, L. R.; Guthrie, P. D. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 67(4):601-606, 1974.

The influence of secretin on biochemical processes related to growth and the relation of such an effect to acid secretion, was studied *in vivo* in male Sprague-Dawley rats. Fasted rats were sacrificed 16 hr after i.p. injections of saline, pentagastrin (250 μg/kg), metiamide (2 mg/kg), secretin (75 U/kg), histamine (20 mg/kg), or combinations of secretin and pentagastrin, or metiamide and pentagastrin. Tissue from the oxyntic gland region, duodenum, and ileum, was incubated for 30 min with [^{3}H]thymidine (2 μc/ml). DNA was extracted, and the incorporation of thymidine was determined by liquid scintillation counting. Results were expressed as disintegrations/min/mg wet weight, or /µg DNA as a percent of the saline-injected control animals. There was no significant difference between these 2 means of expression. Pentagastrin stimulated DNA synthesis to 50, 60, and 100% in duodenal, ileal, and gastric tissues, resp. Neither histamine nor secretin alone affected DNA synthesis in any tissue. Secretin, when given in combination with pentagastrin, completely blocked the stimulation of DNA synthesis. Metiamide, which like secretin, inhibits gastrin-stimulated acid secretion, was ineffective in blocking gastrin-stimulated DNA synthesis. The following conclusions were drawn: 1) the stimulation of DNA synthesis by gastrin is independent of its effect on acid secretion; 2) the stimulation of DNA synthesis by gastrin is prevented by secretin; 3) the antitrophic action of secretin is independent of its effect on gastric acid secretion; and 4) the antitrophic activity of the secretin molecule may depend entirely on the antagonism of gastrin.

9025 A STUDY OF AMINO ACIDS IN THE GASTRIC MUCOSA DURING DIFFERENTIATION AND THEIR SIGNIFICANCE. II. *(E.)* Nishioka, T. (Anat. Dept., Wakayama Med. Univ., Japan). *Experientia* 30(8):938-940, 1974.

The effect of lysine, histidine, arginine, tyrosine and isoleucine on morphological and functional differentiation of gastric mucosa was studied in neonatal Wistar rats born to females treated by daily injections of these amino acids during pregnancy. The results were compared to those of a control group which did not receive amino acids and to those of a third group which was injected daily with a mixture of 15 other amino acids. Morphologic differentiation was assessed from hematoxylin-eosin stained mucosal sections while functional differentiation was determined by the appearance of iron hematoxylin staining granules (presumed to be secretory granules) in gastric chief cells of mucosal sections. Morphologic differentiation appeared to take place 2 days earlier in the experimental group than in either of the two control groups. A similar early pattern of functional differentiation of gastric mucosal cells also occurred in the experimental group on the 3rd postnatal day. Secretory granule appearance and, hence, functional differentiation of gastric mucosal cells of both control groups was not observed until the 13th postnatal day. These results are in accordance with previously published data.

9026 EFFECT OF INTRAVENOUS ACETYLCHOLINE ON SERUM GASTRIN LEVELS IN DOGS. *(E.)* Booth, R. A. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Proc. Soc. Exp. Biol. Med.* 146(4):1156-1158, 1974.

he effect of i.v. acetylcholine infusion on serum astrin levels was studied in 5 normal dogs, in 5 ogs with gastric fistulas placed 6 weeks earlier nd in 6 dogs with total gastrectomy performed 10 eeks earlier. The animals were fasted overnight nd acetylcholine (0.5-6 mg/kg/hr) was infused at ncreasing rates over a 5 hr period during which lood samples were periodically drawn for radioimmunoassay of gastrin. Normal dogs and dogs with total gastrectomy showed no alteration in serum gastrin levels during infusion. However, dogs with gastric fistulas draining the innervated stomach ad an immediate 3-fold increase in serum gastrin uring infusion of toxic doses of acetylcholine (2-6 mg/kg/hr). Gastric acid secretion, which was also increased, did so before either significant alteration in circulating levels of serum gastrin or the onset of toxic signs (restlessness, increased salivation, retching, defecation). It was thus concluded that i.v. acetylcholine can stimulate gastric acid secretion without increasing serum gastrin and that increased gastrin release occurs only if gastric acid is removed from the stomach. The released gastrin arises from the gastric antrum.

9027 A STUDY OF AMYLOPECTIN SULFATE AND BILE DAMAGE TO THE GASTRIC MUCOSAL BARRIER: AN EXPERIMENTAL STUDY WITH CANINE HEIDENHAIN POUCHES.

(E.) Calcraft, B. J.; Rhodes, J.; Cross, S.; Hole, D.; Aubrey, A. (Univ. Hosp. Wales, Cardiff). *Am. J. Dig. Dis.* 19(11):1007-1015, 1974.

The protective action against mucosal damage of a sulfated polysaccharide, amylopectin sulfate, was examined in the Heidenhain pouches of 3 dogs. The net fluxes of hydrogen and sodium ion were measured before, during, and after exposure of the mucosa to a 10 mM bile acid solution at pH 2. The potential difference across gastric mucosa was measured during the experiments. Hydrogen ion back-diffusion from and sodium ion gain by the pouch were significantly increased by bile; there was also a simultaneous fall in potential difference. However, when the pouches were first treated with a 2% aqueous solution of amylopectin sulfate, the net increase in the flux of hydrogen and sodium ion was significantly less after exposure to bile. The fall in potential difference was also significantly less. These results suggest that amylopectin sulfate protects gastric mucosa against the damaging effect of bile.

9028 EFFECT OF ETHYL ALCOHOL ON THE BIOSYNTHESIS OF GLUCOSAMINE AND GALACTOSAMINE IN THE HUMAN GASTRIC MUCOSAL TISSUE IN VITRO. *(E.)*

Glowacka, D.; Kopacz-Jodczyk, T.; Mazurkiewicz-Kilczewska, D.; Gindzienski, A. (Inst. Physiol. Biochem., Bialystok, Poland). *Biochem. Med.* 11(3):199-204, 1974.

The effect of ethanol on the biosynthesis of glucosamine and galactosamine by human gastric mucosa *in vitro* was studied. The slices of human gastric mucosa were incubated in medium containing glucose-^{14}C with or without ethanol. Hexosamines were isolated by using ion-exchange column chromatography and then they were purified and separated by means of preparative paper chromatography. It was shown that human gastric mucosa is able to synthesize both glucosamine and galactosamine from glucose *in vitro*. In the presence of ethanol (5.5%), the biosynthesis of glucosamine is unaffected. Galactosamine biosynthesis, however, is significantly reduced, being 50% of the rate of glucosamine synthesis after 3 hr.

9029 STIMULATED CHLORIDE TRANSPORT BY ISOLATED PARIETAL CELLS. *(E.)*

Glick, D. M. (Med. Coll. Wisconsin, Milwaukee). *Biochem. Pharmacol.* 23(23):3283-3288, 1974.

A preparation of rabbit parietal cells has been shown to respond to effectors of gastric acid secretion. The cells were isolated, aligned at the interface of two aqueous phases, and the transport of Cl^- from one phase to the other effected by the cells under various pharmacological stimuli, was measured. Ca^{2+} (10^{-3} M), in contrast to Mg^{2+} (10^{-3} M), was shown to be necessary to elicit secretions of Cl^- across the interface in response to histamine (10^{-3}M). This response was inhibited by prostaglandin E_1 (10 μg/ml). Dibutyryl cyclic AMP was without effect. Carbachol and catecholamines also stimulated secretion, but this was not inhibited by prostaglandin E_1. Because basal Cl^- transport in the presence of Ca^{2+} is in a direction opposite to that of the stimulated transport (and to the low basal transport in the presence of Mg^{2+}), at least two secretion mechanisms appear operative.

9030 THE EFFECTS OF CARBENOXOLONE ON THE BIOSYNTHESIS OF GASTRIC GLYCOPROTEINS IN THE RAT AND FERRET. *(E.)*

Shillingford, J. S.; Lindup, W. E.; Parke, D. V. (Dept. Biochem., Univ. Surrey, Guildford, England). *Biochem. Soc. Transact.* 2(5):1104-1107, 1974.

The effects of carbenoxolone, which has been shown to accelerate healing of gastric ulcers, have been studied on the *in vitro* incorporation of isotopically labeled hexoses and amino acids into glycoproteins of rat and ferret gastric and duodenal mucosae. Animals received carbenoxolone sodium (25 mg/kg) orally in drinking water for 7 days, were then sacrificed and the stomachs and duodena were removed for the kinetic studies. Compared to control animals, carbenoxolone pretreatment caused enhanced rates of incorporation of N-acetyl[^3H]glucosamine, [^{14}C]-galactosamine, [^3H]glucosamine, [^3H]fucose and N-acetyl[^{14}C]neuraminic acid into acid-insoluble glycoproteins of rat and ferret gastric mucosa. The incorporation rate of [^{14}C]galactose into rat but not ferret gastric mucosa was decreased. Carbenoxolone pretreatment did not produce increased rates of incorporation of these sugars into glycoproteins of duodenal mucosa suggesting a significant difference between the glycosylating enzyme systems of these 2 tissues. It is postulated that carbenoxolone protects the gastric mucosa from ulcer formation by simulating synthesis of a modified glycoprotein which yields a more protective mucus.

9031 PRESENCE OF PROSTAGLANDINS E_2 AND A_2 IN CANINE GASTRIC SECRETIONS. *(E.)* Dozois, R. D.; Thompson, C. J. (Dept. Clin. Surg., Univ. Edinburgh, Scotland). *Life Sci.* 15(5):975-986, 1974.

The presence of prostaglandins was determined in gastric juice obtained from 3 conscious dogs, surgically provided with a chronic gastric fistula. Outputs of acid (mEq/min) and prostaglandins (pg/min) were measured in gastric secretions stimulated by pentagastrin (100 or 200 ng/kg/min). Prostaglandin activity was estimated, after extraction and thin-layer chromatography, by radioimmunoassay of the prostaglandin B formed by treatment with alkali. Tritiated prostaglandins were added to the gastric juice for the purpose of correcting for prostaglandin recovery. Using this method, the minimum mass of prostaglandin B which could be satisfactorily distinguished from zero was 25 pg. Prostaglandins A_2 and E_2 were present in pentagastrin-activated gastric secretions and averaged 200.7 ± 18.1 and 260.1 ± 18.0 pg/min, resp. The identity of prostaglandins A_2 and E_2 was confirmed by gas liquid chromatography combined with mass spectrometry. The amount of prostaglandin E_2 converted to prostaglandin A_2 during extraction, separation and conversion procedures was estimated from the amount of $[^3H]$ prostaglandin A_2 found when only $[^3H]$ prostaglandin E_2 had been added to a sample of gastric juice and averaged 14.5% ± 2.0. The preliminary results support the possibility that prostaglandins E_2 and A_2 may be of physiological importance in the regulation of canine gastric secretions.

9032 ACTION OF ACETYLSALICYLIC ACID AND GLUCAGON ON ACID SECRETION, MUCOSAL BLOOD FLOW, BLEEDING AND NET IONIC EFFLUX IN THE FUNDIC POUCH OF PENTAGASTRIN-STIMULATED DOGS. *(E.)* Lin, T. M.; Warrick, M. W. (Eli Lilly Co., Indianapolis, Ind.). *Arch. Int. Pharmacodyn. Ther.* 210(2):279-287, 1974.

Steady gastric HCl and electrolyte secretion and clearance of plasma aminopyrine were resp. maintained in 4 fasting dogs by continuous infusion of pentagastrin (1.2 µg/kg/hr) and aminopyrine (5 mg/kg/hr). At 1/2 hr intervals 25 ml of 0.1 N HCl were instilled into the Heidenhain pouches of 4 dogs, allowed to remain in the pouch for 30 min and then drained for analysis; the process was repeated for 6 hr. In the 4th-6th periods the instillate contained in addition to HCl, 5 mg/ml of acetylsalicylic acid. Acetylsalicylic acid caused hemorrhage, and loss of plasma transferrin ^{51}Cr from mucosa to lumen, and increases in volume of recoverable instillate, gastric clearance of aminopyrine (mucosal blood flow) and net effluxes of Na+, K+, Ca++ and Mg++ and disappearance of acid from lumen to mucosa. Glucagon at 50 µg/kg s.c. in two doses, reversed the actions of acetylsalicylic acid on volume of recoverable instillate and mucosal blood flow and significantly reduced the loss of hemoglobin and plasma transferrin from mucosa to lumen. But the damaging action of acetylsalicylic acid on the integrity of the Na+ barrier and its effect to increase net Ca++ and Mg++ effluxes were unaffected by glucagon. Glucagon decreased the acetylsalicylic acid-induced net K+ efflux by more than 50%. The H+ concentration in the instillate was decreased by acetylsalicylic acid and was further reduced by glucagon. However, the mechanisms by which acetylsalicylic acid and glucagon caused reduction of net H+ efflux were different, the former by breaking down the H+ barrier and the latter, by suppression of active H+ secretion. The reduction of acetylsalicylic acid induced hemorrhage by glucagon lasted for at least 3 hr. The evidence indicates that glucagon may be therapeutically useful for gastric mucosal bleeding in man.

9033 THE ROLE OF AMINO ACIDS AS STIMULANTS OF ANTRAL RELEASE. *(E.)* Kubacz, G. J. (Roy. Perth Hosp., Australia). *Aust. NZ J. Surg.* 44(2): 186-192, 1974.

Various amino acids commonly found in meat and liver extract were studied to determine their effect on gastrin release in male and female dogs with Heidenhain pouches. Gastrin release was measured indirectly by determining the increase in gastric HCl concentration. Of all amino acids tested, only glycine (0.4-0.8 M) and β-alanine (0.4 M) produced consistent and reliable stimulation of acid secretion following antral irrigation. Maximum acid output, however, was only about 33% that following histamine stimulation by i.v. infusion (40 µg/kg/hr). DL-serine, β-alanine and cysteine were relatively weak stimulants of acid output compared to histamine although they had about 50% of the activity of glycine. Phenylalanine, tyrosine, tryptophan and leucine had almost no stimulatory effect on Heidenhain acid secretion.

9034 QUANTITATIVE CYTOCHEMICAL ESTIMATION OF THE EFFECT OF PENTAGASTRIN (0.005-5 pg/ml) AND OF PLASMA GASTRIN ON THE GUINEA-PIG FUNDUS IN VITRO. *(E.)* Loveridge, N.; Bloom, S. R.; Welbourn, R. B.; Chayen, J. (Kennedy Inst. Rheumatol., London, England). *Clin. Endocrinol.* 3(3):389-396, 1974.

To investigate whether the cytochemical approach to the bioassay of hormones could be applied to measure the effect of known concentrations of gastrin, strips of fundus from the stomach of a female Hartley guinea pig were maintained mucus-side upwards, in the presence of T8 culture medium at pH 7.0. The tissue was maintained *in vitro* for 5 hr after which the culture medium was replaced by bicarbonate-depleted T8 medium, containing either graded concentrations of pentagastrin or 2 dilutions (1:100, 1:1000) of human plasma. After 5 min the tissue was removed and chilled to -70C. Tissues were sectioned at 18 µm, flash-dried and left at room temperature for 5-10 min, after which they were reacted for carbonic anhydrase activity. The amount of reaction product was measured in the parietal cells by a scanning and integrating microdensitometer. A positive linear correlation was found between the mean integrated extinction in the parietal cells and logarithm of the concentration of pentagastrin in the culture medium over the range 0.005-5.0 pg/ml Four strips of fundus were subjected to 4 logarithmic concentrations of pentagastrin and 2 were treated with T8 medium containing 1:100 or 1:1000 dilutions of a human plasma for 5 min. From the calibration graph of e effect of the graded concentrations of pentastrin, the concentration of gastrin activity in e plasma could be calculated. The 2 dilutions gave lues of 100 pg/ml and 80 pg/ml, resp. It was erefore possible, using this cytochemical techque, to measure pentagastrin down to a level of 005 pg/ml (6.5 X 10^{-15} M), and gastrin-like acvity in human plasma at concentrations at least uivalent to, or less than, 0.05 pg/ml (2.3 X 10^{-14} of human gastrin. The results were in reasonable greement with those obtained by radioimmunoassay.

035 INVESTIGATIONS INTO THE REDUCTION OF PEPSIN ACTIVITY BY BILE.

(E.) Tompkins, R. K.; yashi, R. M. (Univ. California Sch. Med., Los Angees). *Am. J. Surg.* 128(5):633-637, 1974.

o further elucidate the mechanism by which canine ile is able to inhibit pepsin activity, *in vitro* tudies were conducted to determine the effects of xidized canine bile and the effects of conjugated anine bile acids on purified porcine pepsin actiity. Oxidized bile had no inhibitory effect on the bility of pepsin to digest an acidified hemoglobin ubstrate. Conjugated bile acids, however, in conentrations from 0.0025 to 0.04 M showed a doseependent inhibitory effect on pepsin activity for epsin concentrations ranging from 10 to 100 μg/0.5 l. The taurine and glycine conjugates of chenoeoxycholic acid were more effective inhibitors than ere the cholic acid conjugates. A sample of human ile with a total bile salt concentration of 0.036 M lso had pepsin-inhibiting activity. These results upport the theory that bile protects the duodenum rom peptic ulceration by inhibiting pepsin activity nd therefore removal of bile by surgical procedures e.g. choledochojejunostomy) may predispose to postperative peptic ulceration.

036 THE EFFECT OF AMYLOPECTIN SULFATE (SN-263) ON THE PEPTIC ACTIVITY OF HUMAN GASTRIC UICE.

(E.) Berstad, A. (Aker Hosp., Oslo, Norway). *cta Hepatogastroenterol.* 21(3):212-220, 1974.

he antipeptic activity of the sulfated polysaccharide amylopectin sulfate (SN-263) was studied using uman gastric juice *in vivo* and *in vitro*. *In vitro* n almost complete reduction of the peptic activity of gastric juice was found by mixing SN-263 with the hemoglobin substrate. The inhibition could be completely overcome by increasing the amount of substrate, but there was still a linear relationship between enzyme concentration and reaction rate also with SN-263, so that, the mechanism of the reduced activity is not substrate depletion. The results suggest that SN-263 does not directly inhibit pepsin to any significant degree, but combines with and masks or makes the substrate protein less digestible by pepsin. Intragastric instillation of 500 mg of SN-263 in 8 healthy volunteers and 1 duodenal ulcer patient only slightly depressed the peptic activity of the gastric content. "Model" experiments with substrate-containing agar on a plate simulating the mucosa and wells in the agar similating peptic ulcers showed that addition of SN-263 to the wells before the addition of gastric juice was not very effective in reducing the peptic digestion, possibly because SN-263 poorly adhered to the agar. However, when SN-263 was melted into the agar, marked reduction of the peptic activity was observed. The results thus confirm that SN-263 can protect the substrate from peptic digestion but to what extent the substance may modify the digestibility of the gastric or duodenal epithelium must to a large extent depend on its ability to adhere to the mucosa *in vivo*.

9037 METHOD FOR ISOLATION AND SEPARATION OF CELLS FROM RAT FUNDIC MUCOSA.

(Fr.) Lewin, M.; Cheret, A. M.; Soumarmon, A.; Girodet, J. (Bichat Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 7(2):139-144, 1974.

The stomach was isolated in vitro as an everted pouch, and diluted pronase was introduced into the interior of the sack. Digestion proceeded for 90 min, and then the stomach was removed. Dissociation continued for another 30 min under magnetic agitation. The extract was filtered, centrifuged twice, and resuspended. Cell separation was effected by taking 15 to 20 ml fractions from a linear density gradient established between 1.05 and 1.30 g/cm^3 by isopycnic equilibration. The yield was estimated at 25%. Oxygen consumption was .2 μM/10^6 cells/hr. The cells were perfectly isolated from each other and fell into 2 groups: 1) clear cells with a mean diameter of 9.5 μ comprising 75% of the total; pepsinogen dye presented an optimum at the zone of density 1.24-1.26, in which zone the mean diameter was 9 μ (the chief cells); this density level included 35% of the chief cells and less than 1% of parietal cells; 2) cells with granular contents comprising 25% of the total; cytochrome c oxydase dye presented an optimum at the zone of density 1.19-1.20, in which zone the mean diameter was 16 μ (parietal cells); at this density level 80% of the cells were parietal. The structural integrity of the cells was satisfactory; the extent of their functional integrity remains to be determined.

9038 EFFECT OF METIAMIDE, A HISTAMINE ANTAGONIST OF H_2-RECEPTORS, ON ACID SECRETION OF ISOLATED CANINE STOMACH PERFUSED WITH HOMOLOGOUS BLOOD.

(E.) Kowalewski, K.; Kolodej, A. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Pharmacology* 11(4):207-212, 1974.

Totally isolated canine stomachs, perfused with homologous blood, were used to study the inhibitory action of metiamide. The stomach was dissected from anesthetized dogs which had been fasted for 48 hr and connected with the perfusion circuit by the preceliac segment of the aorta and the distal portal vein. Oxygenation and dialysis of perfusion blood took place in supporting gastrectomized dogs. Histamine (150 μg/hr) and bethanechol chloride (500 μg/hr) were infused separately or combined into the gastric artery for 6-7 hr. When the base-line secretion was established after 2-3 hr, metiamide (200 μM/hr) was infused for 2 hr, then infusion of the stimulant continued for the remaining 2-3 hr. Under all conditions of stimulation used in this study, metiamide significantly inhibited the concentration and output of HCl. In all stomachs studied there was a complete absence of titrable H+ at a certain stage of metiamide infusion or following such an infusion. These results indicate that the action of metiamide is not selectively limited to the antagonism of H_2-receptors, acting against both H_2-receptors and muscarinic receptors.

9039 BICARBONATE SECRETION IN THE HUMAN STOMACH. *(E.)* Andre, C.; Bruhiere, J.; Vagne, M.; Lambert, R. (INSERM, Edward Herriot Hosp., Lyon, France). *Acta Hepatogastroenterol.* 20(1):62-69, 1973.

The output of bicarbonate, sodium chloride and potassium was studied in 20 healthy patients after a gastric load by buffered glycine test meal. The outputs were compared in basal conditions and after the injection of betazole (Histalog). Under basal conditions, secretion of bicarbonate, chloride and potassium was 1.17, 1.78 and 0.18 mEq/10 min, resp. Sodium was absorbed (mean output of -0.69 mEq/10 min). In the presence of Histalog, increased rates of secretion of bicarbonate (235-266%), chloride (373-580%) and potassium (138-185%) were observed. A significant increase in sodium secretion was also found. The increase in bicarbonate and sodium output pointed to a variation of the alkaline component of gastric juice. Thus, bicarbonate secretion in the human stomach is not steady and increases when the fundic mucosa is stimulated. High concentrations of chloride and bicarbonate are explained by the trapping effect of glycine buffer on hydrogen ions.

Pancreas

050 THE SECRETION OF ALKALI METAL IONS BY THE PERFUSED CAT PANCREAS AS INFLUENCED BY THE OMPOSITION AND OSMOLALITY OF THE EXTERNAL ENVIRON-ENT AND BY INHIBITORS OF METABOLISM AND Na+, K+ ATPase ACTIVITY. *(E.)* Case, R. M.; Scratcherd, T. Jniv. Med. Sch., Newcastle upon Tyne, England). . *Physiol. (Lond.)* 242(2):415-428, 1974.

he mechanisms of the secretion of sodium and potas-ium were studied in isolated cat pancreas; the pos-ibility that sodium is actively transported was lso examined. The pancreas was isolated from cats hich had been fasted for 18 hr and perfused with icarbonate buffered saline solutions of varying omposition and osmolality, and stimulated maximally ith secretin. Under isosmolal conditions (the pan-reatic secretion which occurs when the perfusate smolality is at normal physiological values), when erfusate sodium chloride was replaced by sucrose, odium and potassium secretion were directly related to erfusate sodium concentration, [Na]p. When osmola-ity was varied by increasing or decreasing NaCl oncentration, the secretion of sodium and of potas-ium were maximal at [Na]p of about 120 and 80 mM, esp. When potassium concentration was varied over he range 0-130 mM under isosmolal conditions, secre-ion of potassium and of sodium was maximal at per-usate potassium concentration, [K]p, of about 50 nd 100 mM, resp. Water flux was maximal at a [K]p f 10-15 mM. The concentration of potassium in the ecretion was almost identical with that in the per-usate over the whole concentration range. Replace-ent of perfusate sodium by lithium reduced the olume of secretion. Omission of potassium from the erfusate reduced secretion by about 65%. Secretion as reduced by more than 90% under anaerobic condi-ions and in the presence of dinitrophenol or cya-ide. Removal of glucose from the perfusate reduced ecretion by more than 50% within 30 min. Ouabain, thacrinic acid, and frusimide, known inhibitors of Ja+, K+-ATPase activity, all inhibited pancreatic lectrolyte secretion. From these observations, here are many features of electrolyte transport n the pancreas which bear a marked similarity to echanisms involved in sodium pumps operating in ther tissues. The evidence suggests that the pan-reas may transport sodium actively.

051 CALCIUM EFFLUX AND SECRETION OF α-AMYLASE FROM RAT PANCREAS. *(E.)* Heisler, S. (Univ. Hosp. Ctr., Univ. Sherbrooke, Canada). *Br. J. Pharmacol.* 52(3):387-392, 1974.

The effect of carbachol on rapid changes in calcium metabolism, especially in relation to the secretion of α-amylase from the pancreas was investigated in pancreatic fragments (10-20 mg) from female Sprague-Dawley rats. Tissue was incubated for 30 min in Krebs-Ringer bicarbonate containing either 0.05, 0.1 or 1.0 mM $CaCl_2$, and ^{45}Ca (0.5 μC/ml). The values for ^{45}Ca space were obtained by dividing the amount of ^{45}Ca taken up/g protein of tissue by the concentration of ^{45}Ca/ml of incubation medium. A reduction in extracellular Ca in the pancreas from 1.0 to 0.05 mM increased ^{45}Ca space 1.61 times. The uptake of ^{45}Ca was determined by incubation of pancreatic tissue for various periods of time in medium containing 0.05 mM $CaCl_2$ (0.5 μC ^{45}Ca/ml). The time required to preload the pancreas maximally with ^{45}Ca was 20 min. Pooled pancreatic fragments were preincubated for 30 min with medium containing 0.05 mM $CaCl_2$ and 0.5 μC/ml ^{45}Ca, after which the fragments were incubated with carbachol 10^{-5}M, dibutyryl cyclic AMP 10^{-3}M, and carbachol 10^{-5}M and dibutyryl cyclic AMP 10^{-3}M. Carbachol increased the rate of ^{45}Ca efflux from the tissue and this effect was associated with an increase in the release of α-amylase. Dibutyrl cyclic AMP also caused a secretory response, but did not alter the rate of ^{45}Ca efflux. In combination with carbachol, the dibutyrl cyclic AMP reduced the carbachol-stimulated increase ^{45}Ca efflux while enhancing the release of secretory protein. The stimulatory effect of carbachol on ^{45}Ca efflux continued to be observed when pancreatic tissues were incubated in media containing a high concentration of ethyleneglycolbis (β-aminoethyl)-*N*,*N*'-tetraacetic acid. Atropine, however, blocked the effects of carbachol on both ^{45}Ca efflux and secretion of α-amylase. It is suggested that intracellular calcium can and may sustain stimulus-secretion coupling in the rat exocrine pancreas.

9052 EFFECT OF ETHANOL ON PANCREATIC ENZYME SECRETION. *(E.)* Valenzuela, J. E.; Salinas, J.; Petermann, M. (Sch. Med., Univ. Chile, Santiago). *Gastroenterology* 67(5):991-995, 1974.

The direct effect of ethanol and ingestion of ethanol on amylase secretion was investigated *in vitro* in pigeon pancreas slices. The slices were incubated with ethanol at a final concentration of 0.066 M (0.3%) or 0.132 M (0.6%), considered to be compatible with moderate to severe intoxication *in vivo*. Cholecystokinin-pancreozymin was added separately or together with ethanol, before incubation, in a final concentration of 2 or 4 Crick-Harper-Raper U/ml of medium. Amylase activity was measured at the end of the incubation period. Spontaneous amylase secretion into the incubation media was unaffected by the addition of ethanol. In *in vivo* experiments, ethanol (4 g/kg body weight in a 10% starch solution) was injected into the birds' stomachs, and the animals sacrificed at 2, 4, 8, 12, 16 and 32 hr after alcohol ingestion. Oral ethanol induced amylase release, but the maximal secretory effect occurred when blood ethanol had returned to basal level. The delayed secretory effect of ethanol produced a state in which the pancreas contained a high enzyme concentration. This state may be related to the mechanism that produces alcoholic pancreatitis.

9053 EFFECTS OF STARVATION AND ISLET HORMONES ON THE SYNTHESIS OF AMYLASE IN ISOLATED EXOCRINE PANCREAS OF THE MOUSE. *(E.)* Danielsson,

A.; Marklund, S.; Stigbrand, T. (Dept. Histol., Univ. Umea, Sweden). *Acta Hepatogastroenterol.* 21(4): 289-297, 1974.

The *in vitro* incorporation of L[^{14}C] leucine into amylase and total protein was studied in pieces of exocrine mouse pancreas. Female mice, 6-7 months old, were starved for 24 hr and injected i.p. with glucose and/or diazoxide 6 hr before decapitation. The pancreas was excised and microdissected, and the pieces incubated in a basal medium (a Krebs-Ringer bicarbonate buffer) containing ^{14}C-labeled L-leucine (total concentration, 0.8 mM). After incubation, the pieces of pancreas were sonicated and the homogenates and incubation media analyzed for amylase activity. Amylase was isolated from other pancreatic proteins in a single step, using isoelectric focusing in a polyacrylamide gel. The incorporation of L-leucine into total pancreatic protein was determined by liquid scintillation. The synthesis of both amylase and total protein was decreased by starvation. Administration of glucose to starved mice increased the amylase content in the pancreas. This effect was blocked by the concomitant injection of diazoxide, a potent inhibitor of glucose-induced insulin release. Insulin, glucose or glucagon had no effect on amylase or protein synthesis in mouse pancreas pieces when these substances were added to the *in vitro* incubation media.

SECRETION AND METABOLISM

Hepatobiliary Tract

9057 CYTOTOXIC EFFECT OF ALCOHOL ON LIVER CELLS AND FIBROBLASTS IN VITRO.

(E.) Walker, F.; Elmslie, W.; Fraser, R. A.; Shape, P.E.; Watt, G. C. M. (Dept. Pathol., Univ. Aberdeen, Scotland). *Scott. Med. J.* 19(3):125-127, 1974.

Cultures of liver cells (Chang) and of fibroblasts (3T6) were exposed to media containing up to 1% v/v ethanol. The number of viable cells was determined 3 days later. Liver cell survival decreased progressively at ethanol concentrations over 0.25% v/v while fibroblast survival decreased progressively at concentrations over 0.50% v/v. Thus, ethanol is more toxic to liver cells than to fibroblasts. Compared with a 70% proof spirit derived from ethanol, brandy was significantly more toxic to both liver cells and fibroblasts; gin was more toxic to liver cells but not to fibroblasts; and whisky was not statistically more toxic to either liver cells or fibroblasts. These findings indicate that high congener beverages, such as brandy, are potentially more cirrhogenic than low congener beverages. It is suggested that sufficient alcohol must be ingested to repeatedly raise the blood ethanol concentration above the level at which liver cell necrosis, as opposed to mere degeneration, occurs. This threshold is between 200-320 mg/100 ml.

9058 EFFECT OF DIETARY FRUCTOSE ON IN VITRO AND IN VIVO FATTY ACID SYNTHESIS IN THE RAT.

(E.) Romsos, D. R.; Leveille, G. A. (Dept. Food Sci., Michigan State Univ., East Lansing). *Biochim. Biophys. Acta* 360(1):1-11, 1974.

Diets containing either [U-^{14}]glucose or [U-^{14}]fructose as the only source of carbohydrate were fed to male Sprague-Dawley rats to investigate the effect of substrate concentration on *in vitro* hepatic fatty acid synthesis and to obtain *in vitro* and *in vivo* estimates of the relative contribution of hepatic and extrahepatic tissue to fatty acid synthesis in glucose- and fructose-fed rats. At near physiological substrate concentrations (10 mM), both glucose- and fructose-fed rats incorporated fructose into hepatic fatty acids to a greater extent (2- to 4-fold) than glucose. However, when the substrate concentration was increased to 100 mM, glucose incorporation in fatty acids was much greater than that of fructose (244 ± 32 and 126 ± 30 nM of labeled glucose incorporated for glucose- and fructose-fed animals as compared to 3 ± 1 and 5 ± 1 nM of incorporated fructose for glucose- and fructose-fed animals, resp.). *In vivo* hepatic ATP levels were significantly elevated in rats fed fructose rather than glucose, while high levels of fructose (100 mM) in he incubation medium markedly depressed ATP levels n liver slices as well as inhibiting ^{14}C-acetate ncorporation into fatty acids. *In vivo* estimates f fatty acid synthesis using ^{14}C-acetate and $^{3}H_2O$ ndicated that while the total capacity of the animal o synthesize fatty acids was unchanged, the relative mportance of the liver was increased and that of he extra-hepatic tissues decreased when fructose, ather than glucose, was fed to rats. The magitude of response to dietary fructose was greater hen tritium rather than radiocarbon was utilized.

059 EFFECTS OF THE HYPOCHOLESTEROLEMIC DRUG CLOFIBRATE ON HEPATIC MITOCHONDRIAL BIOENESIS.

(E.) Gear, A. R. L. (Dept. Biochem., Univ. irginia, Charlottesville). *S. Afr. J. Sci.* 70(8): 53, 1974.

n *vitro* and *in vivo* animal studies were performed o assess the effect of the hypocholesterolemic drug lofibrate on hepatic mitochondrial biogenesis. Cloibrate raised hepatic mitochondrial levels in test nimals by over 100%, with a maximum increase occurring 2-4 days after drug administration and a slow ise continuing on day 10. No change in particle ize or specific DNA or RNA content was observed. alf-life measurements with ^{14}C-guanidinio arginine howed no significant clofibrate-induced alterations rom the normal half-life (5.8 days) for mitochondria. he initial rate of short-term ^{35}S-methionine incororation into mitochondria of drug-tested animals was, owever, 40% greater than that for control animals, hile the *in vitro* efficiency of ^{14}C-leucine incororation into mitochondria of drug-treated animals as 61% of that for controls. Enzyme activity of rug-tested animals was not significantly altered or inner membrane or matrix enzymes. A 30-40% fall n specific activity of 3 outer membrane enzymes was, owever, noted from 2-15 days. Clofibrate did inibit the neutral protease activity of mitochondria, ith a 38% inhibition of the control value of 0.334 M amino acid/hr/mg protein observed on day 2. A aximum inhibition of 50% occurred on day 6, and protease activity was still only 63% of its control alue on day 20. *In vitro* additions of clofibrate ad negligible influence on neutral protease activty. Protease inhibition was independent of lysoomes since the activity of the latter was not hanged either in whole homogenates or in the puriied mitochondrial fractions during drug treatment. he findings support the hypothesis that net levels f hepatic mitochondria may be controlled by the ctivity of their own neutral proteases.

060 ISOLATION OF A CARCINO-EMBRYONIC-ANTIGEN (CEA) FROM A LIVER METASTASIS OF PRIMARY DENOCARCINOMA OF THE COLON AND PREPARATION OF THE PECIFIC ANTISERUM.

(E.) Mistretta, A. P.; Bartorelli, A.; Golferini, A.; Tassi, G. C.; De Barbieri, .; Accinni, R. (S. Belfanti Milan Inst. Serum Ther., Italy). *Experientia* 30(10):1209-1210, 1974.

An improved method for carcinoembryonic antigen (CEA) purification suitable for large quantities of material is described. Extraction of a lyophilized powder obtained from freeze-dried supernatant collected from centrifugation of a suspension of 1 kg liver metastases (primary adenocarcinoma of the colon) and equal volumes of water and 2 N perchloric acid according to Meltzer's technique with 3 M potassium chloride removed about 75% of inert substances with no appreciable loss of CEA. The CEA was eluted at a molarity of 0.1 from DEAE-cellulose with the aid of a phosphate buffer. CEA was also detectable in small quantities in the 0.05 M fraction. Elution on Sephadex G-200 gave 3 peaks, with the CEA detectable only in the middle of the 3 peaks. The yield of the purification method was 100-120 mg CEA/kg liver metastases; the whole process took about 3 weeks. The purified CEA, when compared with a reference antigen at the same concentration, showed the same specific activity and equal binding capacity after labeling. Immunoelectrophoresis of the purified CEA showed only 1 band when the antigen was tested against either anti-CEA or anti-liver metastases antiserum obtained from Pearbright White guinea pigs. No bands were observed when the CEA was tested against normal guinea pig anti-liver antiserum.

9061 TRANSCRIPTIONAL CONTROL OF α-FOETOPROTEIN SYNTHESIS IN DEVELOPING MOUSE LIVER.

(E.) Koga, K.; O'Keefe, D. W.; Iio, T.; Tamaoki, T. (Univ. Alberta Cancer Res. Unit, Edmonton, Canada). *Nature (Lond.).* 252(5483):495-497, 1974.

RNA was extracted from polysomes of fetal (14 day) and adult ICR mouse liver and measured for its ability to direct the synthesis of α-fetoprotein in cell-free systems to determine whether the decrease in α-fetoprotein in adult liver is due to an alteration in messenger-RNA synthesis or in m-RNA translation. Some of the extracts were further fractionated into ribosomal washes (high-salt extracts upon which the translation of polysomal RNA depends). Polyacrylamide gel electrophoretic analysis of proteins produced in the fetal liver cell-free system in the presence of fetal polysomal RNA and fetal ribosomal wash revealed 4 main fractions, 2 of which comigrated with carrier α-fetoprotein and albumin, resp. The substitution of fetal ribosomes and high speed supernatant fraction with adult counterparts did not affect the synthesis of fetoprotein, suggesting that either messenger RNA or ribosomal wash was responsible for the regulation of α-fetoprotein synthesis. When fetal polysomal RNA was used as a template, α-fetoprotein synthesis exceeded albumin synthesis. (used as an internal control) 2- to 3-fold with either fetal or adult ribosomal wash. When adult polysomal RNA was used as the template, the synthesis of α-fetoprotein decreased drastically with either fetal or adult ribosomal wash. Albumin synthesis was relatively unchanged, and thus the ratio of α-fetoprotein to albumin synthesis decreased. These results indicated that α-fetoprotein messenger RNA was deficient in the adult polysomal RNA, although the factors necessary for its translation were present in adult liver. The possibility that active α-fetoprotein messenger RNA might be present in the nucleus or in the cytoplasm in a free form was tested by fractionating the adult liver into nuclei and cytoplasm, extracting RNA from each fraction, and measuring its ability to synthesize α-fetoprotein and albumin. Synthesis of α-fetoprotein by nuclear or cytoplasmic RNA was small, suggesting that the level of α-fetoprotein messenger RNA in adult liver is greatly reduced. The possibility that α-fetoprotein messenger RNA was degraded during extraction from adult liver was ruled out since albumin messenger RNA was extracted in an active form from the same source.

9062 ACTION OF METHANETHIOL ON NA$^+$, K$^+$-ATPASE: IMPLICATIONS FOR HEPATIC COMA. *(E.)* Foster, D.; Ahmed, K.; Zieve, L. (Minneapolis VA Hosp., Minn.). *Ann. NY Acad. Sci.* 242:573-576, 1974.

The action of methanethiol on the rat brain sodium-, potassium-ATPase system was investigated in terms of its possible molecular site of action and its implications for hepatic coma in humans. Various amounts of methanethiol were added to 10 μg of enzyme protein (incubated for 10 min at 37 C) in a sealed reaction tube, and specific activities for sodium- and potassium-stimulated ATPase and potassium-stimulated *p*-nitrophenylphosphatase were recorded. The introduction of increasing amounts of methanethiol (0.19-1.90 μM) resulted in increasing inhibition of the ATPase system (46%-74%), though the response to inhibitor concentration was not linear. The potassium-stimulated *p*-nitrophenylphosphatase system was not inhibited, but was slightly stimulated, under similar conditions. A comparison of the effect of compounds related to methanethiol on the sodium-, potassium-ATPase system showed the following declining order of inhibitor potency: methanethiol, ethanethiol, and dimethyl sulfide (45, 44, and 18% inhibition, resp.). Dithiothreitol and 2-mercaptoethanol did not influence the ATPase system activity nor did they reduce the inhibitory effect of methanethiol on the enzyme. A comparison of the effects of methanethiol on the mitochondrial ATP-phosphate exchange reaction and on the microsomal membrane sodium, potassium-ATPase activity revealed that the former was essentially unaltered by methanethiol, suggesting that the mercaptan may be selective in its action on membranes and that the sodium-, potassium-ATPase may be a preferred site. The primary site of action of methanethiol on the sodium-, potassium-ATPase system appears to be the sodium-dependent portion of the sequence. Prolonged exposure to methanethiol, for example in chronic hepatic coma, may result in inhibition of the ATPase system as a consequence of increased concentrations of methanethiol and other mercaptans in the nerve cell membrane.

9063 FUNCTIONAL REGENERATION IN LIVER OF OLD RATS AFTER PARTIAL HEPATECTOMY. *(E.)* Obenrader, M.; Chen, J.; Ove, P.; Lansing, A. I. (Univ. Pittsburgh Sch. Med., Pa.). *Exp. Gerontol.* 9(4):181-190, 1974.

Ferritin metabolism and albumin synthesis were investigated in regenerating liver sections from partially hepatectomized young (4-6 week-old) and old 17-20 month-old) female Fisher rats to investigate whether changes in liver protein metabolism occurring with age are due to somatic mutations. Regenerating rat liver from old animals appeared to regain the functional properties of young rat liver, suggesting that the metabolic changes associated with age are not due to changes in the genome. Albumin synthesis, elevated in old animals, returned to young rat levels in old rats for several weeks after the partial hepatectomy. Old rat ferritin also underwent changes in regenerating liver. The amount of ferritin iron/g liver fell to about 1/2 its previous value 1 week following partial hepatectomy and the amount of iron/mg ferritin protein also dropped by about the same proportion during the same time period. However, the amount of ferritin protein/g liver remained constant in regenerated old rat liver. The half-life of ferritin in regenerated old rat liver (2.3 days) was much shorter than in old rat liver controls (3.9 days) and approached that of young rat liver ferritin (2.1 days). The functional properties of old rat liver were restored 12 weeks following partial hepatectomy.

9064 ALPHA$_1$-FETOPROTEIN BIOSYNTHESIS DURING THE GROWTH CYCLE OF DIFFERENTIATED FETAL RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. *(E.)* Leffert, H. L.; Sell, S. (Salk Inst., San Diego, Calif.). *J. Cell Biol.* 61(3):823-829, 1974.

The production of α_1-fetoprotein by primary cultures of differentiated fetal rat hepatocytes was studied by radioimmunoassay. Logarithmically replicating cells showed a 10-fold increase in accumulated radioimmunoassayable α_1-fetoprotein (> 1000 ng/ml) from the 1st to the 6th day after seeding of the cultures. Cultured fetal rat fibroblasts showed no such increase from a small, basal rate of production (70-80 ng/ml). Log phase hepatocyte cultures released 6 times as much ^{3}H-leucine-labeled fetoprotein into the medium as did lag phase cultures (i.e., within 24 hr after seeding). The amount released declined as log phase cultures became confluent and entered contact inhibition of growth. The appearance of ^{3}H-leucine-labeled α_1-fetoprotein in the medium was also inhibited by cycloheximide (5 μg/ml). Studies of α_1-fetoprotein synthesis in stationary cultures stimulated to undergo a round of DNA synthesis and cell division by refeeding with fresh medium showed that α_1-fetoprotein synthesis was first detected 8 to 10 hr after the first wave of DNA synthesis and was maximal 5 to 6 hr after the first cells entered mitosis.

9065 EFFECT OF CHRYSENE AND CARBON TETRACHLORIDE ADMINISTRATION ON RAT HEPATIC MICROSOMAL MONOOXYGENASE AND UDPGLUCURONOSYLTRANSFERASE ACTIVITY *(E.)* Aitio, A. (Dept. Physiol., Univ. Turku, Finland). *FEBS Lett.* 42(1):46-49, 1974.

The activities of rat hepatic microsomal aryl hydrocarbon hydroxylase and uridine 5'-diphosphate (UDP) glucuronosyltransferase were determined 24 hr following treatment with either chrysene (20 mg/kg i.p.) or CCl$_4$ (1 ml/kg by gastric intubation). CCl$_4$ produced more than a 50% decrease in aryl hydrocarbon hydroxylase activity as well as a concomitant 75% decrease in cytochrome P450 content. UDP glycorunosyltransferase activity was stimulated 2-fold by CCl_4, and this evidently due to activation rather than induction since digitonin-treated microsomes showed decreased activity.

9066 HEPATIC NECROSIS CAUSED BY FUROSEMIDE. *(E.)*

Mitchell, J. R.; Potter, W. Z.; Hinson, J. A.; Jollow, J. D. J. (Natl. Heart Lung Inst., Natl. Bethesda, Md.). *Nature* [illegible] 251(5475):508-511, 1974.

The diuretic, furosemide, was converted by a microsomal enzymes in the liver of mice and humans to a reactive arylating metabolite which produced massive hepatic necrosis in mice. Histologic study of liver sections from male Swiss albino mice at various times after i.p. instillation of furosemide (400 mg/kg) at greater than therapeutic doses demonstrated single cell unaffected. Studies using different furosemide conseverely damaged livers showed massive midzonal and centrilobular necrosis. Kupffer cells were generally unaffected. Studies using different furosemide concentrations showed that the effect was dose-dependent. Liver damage was prevented when metabolism of furosemide was prevented by pretreatment of mice with 3 different types of cytochrome P-450 enzyme inhibitors. *In vitro* covalent binding of ^{3}H-furosemide or ^{32}S-furosemide to hepatic microsomal proteins required oxygen and a reduced nicotinamide-adenine dinucleotide phosphate generating system. An arylating metabolite was detected covalently bound to microsomal protein leading to the conclusion that the arylation of liver macromolecules by a reactive furosemide metabolite is causally related to the development of furosemide-induced hepatic necrosis.

9067 HEPATIC KETOGENESIS AND GLUCONEOGENESIS IN HUMANS. *(E.)*

Garber, A. J.; Menzel, P. H.; Boden, G.; Owen, O. E. (Temple Univ. Hlth. Sci. Ctr., Phila., Pa.). *J. Clin. Invest.* 54(4): 981-989, 1974.

Hepatic ketone-body production was studied in 5 human volunteers following a 3 day fast. In addition, hepatic gluconeogenesis as well as the relationship between ketogenesis and gluconeogenesis were evaluated. Toward this end, differences in free fatty acid, triglyceride, acetoacetate, β-hydroxybutyrate, oxygen, carbon dioxide, glucose, lactose, pyruvate, glycerol and alanine concentrations between the splanchnic arteries and hepatic vein were determined. Although splanchnic production of both β-hydroxybutyrate and acetoacetate were equal (total of 115 g/24 hr), there was a relative predominance of β-hydroxybutyrate in the hepatic vein. This rate of hepatic ketogenesis was comparable to that previously noted after 5-6 weeks of starvation. Since the degree of peripheral hyperketonemia after 5-6 weeks of starvation was 3-fold greater, the rate of removal of ketone-bodies by peripheral tissues is probably as important as the rate of production in determining peripheral blood ketone levels. Splanchnic glucose release was 123 g/24 hr, a rate slower than that previously observed after an overnight fast but greater than that seen during prolonged starvation. Hepatic gluconeogenesis, as calculated from the sum of hepatic vein lactate, pyruvate, glycerol and amino acids was 99 g/24 hr, a value greater than that seen after either an overnight fast or prolonged starvation. The rate of hepatic ketogenesis showed a direct relationship to the rate of gluconeogenesis.

9068 HISTOCHEMICAL STUDIES OF HEPATIC ENZYMES IN DOGS SUBJECTED TO LOBAR BILE DUCT OBSTRUCTION. *(E.)*

Hagerstrand, I.; Nordén, J. G.; Ohlsson, E. G. (Malmo Gen. Hosp., Sweden). *Acta Chir. Scand.* 140(5):391-395, 1974.

Liver morphology and enzyme histochemical changes were studied in 12 dogs following surgical left lateral and medial lobar bile duct obstruction, and findings were compared to those in 8 dogs following sham abdominal operation. Biopsy specimens from obstructed lobes 4 weeks after surgery showed proliferation of connective tissue with bile ductile proliferation and occasional chronic inflammation. Obstructed lobes gradually atrophied. Glycogen content of obstructed hepatocytes as demonstrated by PAS-MacManus staining was decreased. No fatty changes of significance occurred. No changes occurred in intracellular succinic dehydrogenase, monoaminooxidase, lactic dehydrogenase and nonspecific esterase staining following bile duct obstruction. Changes, however, did occur in the intracellular distribution and/or intensity of reaction of glucose-6-phosphatase. Canalicular alkaline phosphatase activity was increased in liver biopsy specimens from both obstructed and nonobstructed lobes and was maintained at increased levels for at least 4 weeks. Serum alkaline phosphatase activity was also increased, reaching peak levels after 1 week but remaining elevated for 4 weeks.

9069 HEPATIC BLOOD FLOW CHANGES FOLLOWING INTRAVENOUS INFUSION OF VARIOUS SINGLE AMINO ACIDS IN DOGS. III. *(E.)*

Hallberg, D.; Soda, M. (Surg. Res. Lab., Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 140(5):388-390, 1974.

Measurements were made of hepatic blood flow in 10 pentobarbital anesthetized dogs using an electromagnetic square wave flowmeter during i.v. infusion of single amino acids. The effects of 18 different amino acids (50 mM/liter) were studied during infusion into the femoral vein at a rate of 16 ml/min (total 100 ml). All amino acids tested increased both hepatic artery and portal vein blood flow. Compared to basal, preinfusion values, phenylalanine, threonine and arginine produced the greatest (26%) increase in portal vein blood flow while lysine, cysteine and tryptophan showed the least increase (about 13%). Histidine, isoleucine and glycine produced the greatest (16%) increase in hepatic artery blood flow. There was no systemic difference in the degree of effect between essential and non-essential amino acids. Systemic arterial blood pressure did not increase during the infusions. Possible mechanisms which may be responsible for these effects include amino acid induced release of glucagon, secretin or cholecystokinin, as well as a direct effect on vessel walls.

9070 STUDIES ON THE DIFFERENTIAL RESPONSE TO GLUCAGON CONCENTRATION ON GLUCONEOGENESIS IN ISOLATED HEPATOCYTES CONTAINING HIGH AND LOW GLYCOGEN.

(E.) Wagle, S. R. (Indiana Univ. Sch. Med., Indianapolis). *Biochem. Biophys. Res. Commun.* 59(4): 1366-1372, 1974.

The effect of various concentrations of glucagon on gluconeogenesis in isolated hepatocytes from fed and fasted Cox rats was studied. Approximately 5-7 μM of glucose was synthesized by fed rats when lactate (5mM), alanine (5mM), and pyruvate (5mM) were used as substrates. Addition of 10^{-12} M glucagon to the isolated hepatocytes stimulated gluconeogenesis, and a 2-fold increase was observed when glucagon concentration was increased to 10^{-10} M. No further stimulation was observed for an additional increase to 10^{-8} M. Glucagon also stimulated the incorporation of labeled lactate and alanine into glucose. In fasted rats glucagon at a concentration of 10^{-12} M had no effect on gluconeogenesis, while concentrations of 10^{-10} to 10^{-8} M stimulated gluconeogenesis by almost 2-fold. Addition of insulin (33 μU/ml) inhibited glucagon-stimulated gluconeogenesis in cells obtained from fasted rats but had no effect in cells obtained from fed rats. The initial cyclic AMP levels were 1.1 ± 0.2 pM/mg protein in fed cells, 2.5 ± 0.5 in fed cells exposed to 10^{-8} M glucagon, and 20.3 ± 5 for fasted cells with 10^{-8} M glucagon. These results show that glucagon is involved in gluconeogenesis in normal homeostasis where it functions without altering cyclic AMP levels as well as in the fasting state, where higher concentrations of this hormone are needed (with a simultaneous decrease in insulin levels) to increase cyclic AMP levels which in turn may control other anabolic processes. It was also observed that the addition of hyaluronidase along with collagenase to cell perfusions from fed rats significantly decreased intracellular glycogen levels. The initial liver glycogen level was 340 ± 60 μM glucose/g as compared to 220 ± 40 μM glucose/g for cells isolated with collagenase alone and 130 ± 35 μM glucose/g for cells isolated with collagenase and hyaluronidase.

9071 BIOSYNTHESIS OF MOLECULAR SPECIES OF PHOSPHATIDYLCHOLINES IN BILE, LIVER AND PLASMA OF RATS GIVEN $[1,1\text{-}^{2}H_{2}]$ ETHANOL.

(E.) Curstedt, T. (Karolinska Inst., Stockholm, Sweden). *Biochim. Biophys. Acta* 369(2):196-208, 1974.

The incorporation of deuterium into different positions of glucose in plasma, *sn*-glycero-3-phosphate in liver, and the glycerol moiety of individual molecular species of phosphatidylcholines in bile, liver, and plasma was studied. Bile fistula female Sprague-Dawley rats were given 0.5-1.5 ml of [1,1- H]ethanol diluted to 10% (weight/volume) in saline and administered i.p. once every hr for 2-24 hr. The distribution of deuterium between the different positions of the glycerol moiety of phosphatidylcholines was the same for all major molecular species in bile, liver and plasma. Deuterium excess, calculated for molecules synthesized *de novo*, was also the same for all molecular species studied and remained constant throughout the experiment. The mean excess was 9 atom% at C-1, 41 atom% at C-2, and 18 atom% at C-3 of the glycerol moiety. The deuterium-labeling at C-2 of the glycerol moiety of phosphatidylcholines was 2-3 times higher than that at C-2 of total hepatic *sn*-glycero-3-phosphate, indicating that a specific pool of *sn*-glycero-3-phosphate was used for the synthesis of phosphatidylcholines in bile, liver, and plasma and that this pool was closely coupled to ethanol oxidation. A comparison of the deuterium-labeling at C-3 of the glycerol moiety with that at C-1 and C-6 of glucose indicated that the major part of the glycerol moieties of phosphatidylcholines in bile, liver, and plasma was formed *via* a gluconeogenetic pathway. Calculated apparent half-life times for the glycerol moieties were different for individual molecular species and varied between 1 and 30 hr. Corresponding species in liver and bile had about the same apparent half-life times, with the exception of 1,2-dipalmitoylphosphatidylcholine which displayed a half-time for the liver that was 10 times longer than that for bile. The apparent half-life times of molecular species in plasma were about 40-50% longer than those of the corresponding species in liver. All of the major phosphatidylcholines in bile, liver and plasma, with the possible exception of the 1,2-dipalmitoyl species, appear to be derived from the same pool in the liver.

9072 THE IDENTITY OF GLUTATHIONE S-TRANSFERASE B WITH LIGANDIN, A MAJOR BINDING PROTEIN OF LIVER.

(E.) Habig, W. H.; Pabst, M. J.; Fleischner, G.; Gatmaitan, Z.; Arias, I. M; Jakoby, W. B. (Natl. Inst. Arthritis Metab. Dig. Dis., Bethesda, Md.). *Proc. Natl. Acad. Sci. USA* 71(10):3879-3882, 1974.

Evidence is presented that ligandin, an intracellula liver protein involved in the binding of such anions as bilirubin, idocyanine green, and penicillin, is identical to glutathione *S*-transferase B, an enzyme catalyzing the conjugation of glutathione with such electrophiles as 1-chloro-2,4-dinitrobenzene, 1,2-dichloro-4-nitrobenzene, iodomethane, ethacrynic acid, and bromosulfophtalein. Homogeneous preparations of glutathione transferase B and ligandin showed the same activity in conjugating these electrophiles with glutathione. Monospecific goat immunoglobulin G (IgG) obtained by immunization with ligandin yielded a single line of identity with transferase B and ligandin when tested by Ouchterlony immunodiffusion techniques or by immunoelectrophoresis. In the precipitin reaction, ligandin and transferase B reacted identically with antibody prepared against ligandin. Amino acid analyses of ligandin and transferase B (both proteins having a molecular weight of 45,000) were identical. Phenobarbital administratio (8 mg/100 g body weight s.c. for 10 days) to littermate Sprague-Dawley rats resulted in an increased activity of liver extracts with 1-chloro-2,4-dinitrobenzene, 1,2-dichloro-4-nitrobenzene, and iodomethane

:eatment of the rat liver extracts with antibody to
igandin and comparison of the remaining enzyme ac-
ivity after removal of precipitated protein with
iat of the same extract after treatment with normal
;G revealed increased activities for both trans-
erase B and ligandin in animals given phenobarbital.
inding activity experiments with indocyanine green,
ilirubin, and benzyl penicillin yielded similar re-
ılts for ligandin and transferase B. Because of
ıe effect of indocyanine green on the conjugation
f 1-chloro-2,4-dinitrobenzene it was concluded that
ıe dye is a competitive inhibitor of the reaction.
ince liver extracts contain at least 3 times as much
igandin as all other glutathione transferases com-
ined, it is postulated that the protein performs a
ıysiological role as a catalyst in addition to its
inding function in cellular transport.

)73 THE CONTROL OF FATTY ACID SYNTHESIS BY SUBSTRATE SUPPLY IN THE PERFUSED MOUSE VER.

(E.) Michael, D.; Salmon, W.; Hems, D. A.
ept. Biochem., Imperial Coll. Sci. Technol., Lon-
n, England). *Biochem. Soc. Trans.* 2(5):1011-1014,
74.

ntrol of fatty acid synthesis by substrate supply
s investigated in perfused livers of normal and
netically obese (ob/ob) female mice. The total
te of hepatic fatty acid synthesis was obtained
om the incorporation of ^3H from ^3H_2O into fatty
ids between 2 and 3 hr. The incorporation of ^{14}C
om ^{14}C-labeled precursors added to the medium pro-
ded a simultaneous measure of the contribution of
rbon from the precursor to the total utilized in
tty acid synthesis. An approximately constant
te of fatty acid synthesis was obtained when livers
om normal mice were perfused with initial glucose
ncentrations between 4 and 15 mM and was increased
higher glucose concentrations. Livers from ob/ob
ce (perfusate glucose initially 6 mM) did not show
increased accumulation of synthesized fatty acid
mpared to the livers of normal mice, until 3 hr
perfusion, by which time the perfusate glucose
d lactate concentrations had equilibrated at about
and 3 mM, resp. Rates of fatty acid synthesis in
vers from normal and ob/ob mice during the 3rd hr
perfusion were similar to those found in previous
vivo studies with ^3H_2O. The fraction of ^3H-la-
led fatty acid found in the medium after 3 hr of
rfusion was 0.25 ± 0.01 and 0.19 ± 0.07 of that
the liver for ob/ob and normal mice, resp. Ad-
tion of lactate to the medium (initially 10 mM)
perfusions in normal mice markedly altered the
pendence of fatty acid synthesis on glucose con-
ntration, such that a rate of 5.9 μM of fatty acid
nthesized/hr/g wet liver was found at 12-17 mM
ucose compared with 1.9 when lactate was omitted.
e presence of lactate at glucose concentrations
4-10 or 20-25 mM, however, exerted little effect
the rate of fatty acid synthesis. The contribu-
on of glucose carbon to the total utilized in
tty acid synthesis increased from 10% at 5 mM to
% at 25-32 mM. When lactate (10 mM) was present,
is precursor provided 25-50% of the carbon utiliz-
in fatty acid synthesis at all glucose concen-
ations. Entry of lactate to the liver may be important in the control of hepatic fatty acid synthesis in the ob/ob mouse.

9074 EFFECT OF PHENOBARBITAL ON CHOLINE UPTAKE IN THE ISOLATED PERFUSED RAT LIVER. *(E.)*

Sorrell, M. F.; Tuma, D. J.; Barak, A. J. (VA Hosp., Omaha, Nebraska). *Pharmacology* 11(6):365-372, 1974.

The effects of circulated phenobarbital and chronic phenobarbital administration on choline uptake and metabolism were studied in isolated perfused livers from Sprague-Dawley rats and Dunkin Hartley guinea pigs. Choline uptake in rat liver was reduced from 1.70 ± 0.16 to 0.9 ± 0.18 mg/g fresh liver 60 min after the addition of 0.5 mg/ml phenobarbital. Addition of the same amount of phenobarbital to perfused guinea pig liver resulted in a reduction in choline uptake from 0.70 ± 0.04 to 0.45 ± 0.47 after 60 min. The inhibitory effects of the drug were linearly dose-dependent. Pretreatment of rats with phenobarbital (50 mg/12 hr i.p. for 5 days) did not significantly affect the choline uptake mechanism in the liver. Radiorespirometric evaluation of the effect of phenobarbital on direct choline oxidation by the isolated perfused rat liver indicated that the drug inhibits the generation of $^{14}CO_2$ from labeled choline supplement during 3 hr of perfusion by approximately 37%, reflecting an inhibition of the choline oxidative pathway to this extent. The effects of phenobarbital on hepatic choline uptake appear to be inhibitory, yet reversible once the drug is removed. The inhibition of choline oxidation by phenobarbital may describe only 1 effect of the drug on hepatic choline uptake.

9075 ANALYTICAL SUBCELLULAR FRACTIONATION STUDIES ON HUMAN LIVER BIOPSIES. *(E.)*

Seymour, C. A.; Neale, G.; Peters, T. J. (Roy. Postgrad. Med. Sch., London, England). *Biochem. Soc. Trans.* 2(5):1101-1104, 1974.

Microanalytical subcellular fractionation techniques were applied to human liver biopsies. Enzyme activities for subjects with normal serum liver function tests and histologically normal liver were as follows: 5'-nucleotidase, 1.10 at pH 9; alkaline phosphatase, 0.918 at pH 9.5; leucyl-β-naphthylamidase, 0.817 at pH 6.8; γ-glutamyl transpeptidase, 2.93 at pH 8.5; *N*-acetyl-β-glucosaminidase, 2.02 at pH 5.7; acid phosphatase, 10.3 at pH 4.4; β-glucuronidase, 4.72 at pH 4.0; β-glucosidase, 0.374 at pH 5.8; and α-glucosidase, 0.391 mU/mg protein at pH 4.5. The distribution of marker enzymes for lysosomes (*N*-acetyl-β-glucosaminidase), peroxisomes (catalase), and mitochondria (malate dehydrogenase) in a human liver biopsy extract were also obtained. These 3 organelles were clearly resolved in the gradient, with the mitochondria (modal density 1.19) and peroxisomes (modal density 1.23) having similar properties to those of rat liver. The particulate activity showed a broad band with an ill-defined modal density at 1.17 as compared to a modal density of 1.23 for rat liver. *N*-Acetyl-β-glucosaminidase showed a complex distribution with much activity remaining in the sample layer. Other acid hydrolases and acid phosphatase had similar distributions to that of *N*-acetyl-β-glucosaminidase. The demonstration of latent and sedimentable acid hydrolase activities established biochemically the presence of lysosomes in the cell extracts. Distinct peaks of particulate activity were obtained for the membrane-bound enzymes. Alkaline phosphatase had a modal density similar to that of 5'-nucleotidase (1.13), but more of the former enzyme was found at higher densities in the gradient, indicating that the phosphatase is largely localized to the plasma membrane in liver. Protein was largely recovered in the sample layer. Leucyl-β-naphthylamidase showed significant amounts of activity in the sample layer and a broad distribution throughout the gradient. Peaks of activity corresponding to 5'-nucleotidase (plasma membrane), *N*-acetyl-β-glucosaminidase (lysosomal), and neutral α-glucosidase (microsomal) suggested a multi-organelle localization. γ-Glutamyl transpeptidase showed little soluble activity and a complex distribution pattern not conforming to any of the marker enzymes. Preliminary results from the application of these techniques to liver tissue from various hepatic diseases indicated a significant positive correlation between serum and tissue activities for enzymes predominantly localized to the plasma membranes.

9076 HISTOCHEMICAL DEMONSTRATION OF γ-GLUTAMYLTRANSPEPTIDASE IN RAT LIVER AFTER PORTACAVAL ANASTOMOSIS. *(E.)* Muller, E.; Colombo, J. P.; Peheim, E.; Bircher, J. (Anat. Inst., Univ. Zurich, Switzerland). *Experientia* 30(10):1128-1129, 1974.

The presence of γ-glutamyltranspeptidase (GGTP) in rat liver after portacaval anastomosis is histochemically demonstrated and compared to its distribution in fetal and neonatal rats. After portacaval shunt, the hepatocytes around the hepatic lobules showed the 1st signs of enzymatic activity, followed by liver cells between the periportal areas and the middle of the lobule. In the postnatal period, the enzyme was gradually localized towards the periportal areas of the lobuli, whereas at the 10th day after birth the activity was as low as in the adult rat. The enzyme fluctuation in the postnatal period and after deviation of portal blood supply can be understood in terms of the fine circulatory situation in the hepatic lobulus. Hepatocytes situated close to the axial terminal branches (vena portae and arteria hepatica propria) are the first to be supplied with fresh blood rich in oxygen and nutrients; these hepatocytes were also the last to stop synthesizing GGTP in the postnatal period and the first to resynthesize GGTP after portacaval shunt. Whether the high enzyme activity in shunted rats is due to the change in substrate or oxygen supply, or both, requires further investigation.

9077 A COMPARISON OF THE PHOSPHOFRUCTOKINASE ISOENZYME PROFILES OF TRANSPLANTABLE HEPATOMAS AND NORMAL LIVER. *(E.)* Kirby, W.; Morris, H. P.; Taylor, C. B. (Dept. Biochem., Univ. Sheffield, England). *Eur. J. Cancer.* 10(9):629-631, 1974.

Phosphofructokinase isoenzyme profiles of transplantable hepatomas with widely differing growth rates and states of differentiation and of normal liver preparations were studied to investigate whether forms of the isoenzyme not present in normal liver occur in hepatomas. The hepatoma material used was from Morris hepatomas 9618A, 16, and 7777 (highly differentiated, well differentiated, and poorly differentiated, resp.) and from Novikoff ascites hepatoma cells (very poorly differentiated). The total phosphofructokinase activity was similar in liver (2.8 U/g wet weight) and tumor 9618A (2.7 U/g), where the less well differentiated tumors 16 (4.5 U/g), 777 (7.8 U/g), and Novikoff cells (23 U/ 1 packed cells) showed progressively higher activities. All tumors showed differences in isoenzyme composition from that of the rat liver, but the changes were within the range of isoenzyme types found in the liver. Moreover, there was no obvious correlation between the change in the isoenzyme pattern and the degree of differentiation. No evidence of new forms of phosphofructokinase in tumors was thus found. When equivalent amounts of the kinase in supernatant fluid from tumors and whole liver were allowed to react with excess antiserum, raised against rat muscle phosphofructokinase, and the residual activity determined after centrifugation, greater proportions of kinase activity precipitated from the tumor were not found in comparison to supernatant activities from the liver. This was consistent with chromatographic results indicating that no muscle-type enzymes are produced by the tumors.

9078 CHANGES IN IN VIVO METABOLISM OF BILE ACID IN THE RAT AFTER TREATMENT WITH PHENOBARBITAL. *(E.)* Cronholm, T.; Einarsson, K.; Gustafsso J. A. (Dept. Chem., Karolinska Inst., Stockholm, Sweden). *Lipids* 9(11):844-849, 1974.

Phenobarbital was administered i.p. (100 mg/kg body weight/day) for 10 days to 3 of 6 male Sprague-Dawle rats to investigate the drug's effect on the pool size and turnover of i.p. administered 24-^{14}C-cholic acid (0.1 mg) and ^{3}H-chenodeoxycholic acid (0.5 mg) given at the end of the experimental period. The ph nobarbital-treated rats had a smaller cholic acid pool compared to control rats (6.08 ± 2.09 mg and 23.60 ± 7.66 mg, resp.), though the pool size of chenodeoxycholic acid, and its metabolites (α- and β-muricholic acids), was of the same magnitude for both groups. The daily production of cholic acid was also decreased in phenobarbital-treated rats compared to controls (2.12 ± 0.46 mg and 7.24 ± 1.66 mg resp.). No significant difference was observed between the synthesis of chenodeoxycholic acid in the 2 groups. The results support the view that various species and strains of mammals show differences in their ability to induce liver enzyme activities during drug treatment since, in contrast to the rat, ma and monkey increase the synthesis of bile acids during treatment with phenobarbital.

9079 AMINO ACID INCORPORATION INTO LIVER PROTEINS DURING EXTRAHEPATIC CHOLESTASIS IN THE RAT. *(E.)* Lundborg, H.; Hamberger, A. (Sahlgrenska Hosp., Goteborg, Sweden). *Eur. Surg. Res.* 6(2):95-109, 1974.

Liver tissue from cholestatic (bile duct ligation) and normal male Sprague-Dawley rats was incubated balanced salt media L-(4,5-^{3}H)-leucine or L-(U-^{14}C)-ucine to study *in vitro* incorporation of leucine to liver slice protein. The cholestatic liver owed a rate of amino acid incorporation which was proximately 3 times that of control liver. There s no apparent effect on the specific radioactivity the precursor. Protein radioactivity increased all subcellular fractions, with the largest inease (300%) being observed for the soluble proins. The microsomes showed a 50% increase in anals ligated for 12 days. Serum from control or olestatic animals and bile from control animals ded during incubation of liver slices had a small fect on leucine incorporation. Brain, kidney, d heart were studied in a similar way to investite whether the effect of cholestasis on protein nthesis was specific for liver. No marked effect amino acid incorporation was observed.

80 ROLE OF THE SODIUM PUMP IN THE REGULATION OF LIVER METABOLISM IN EXPERIMENTAL ALCOLISM.

(E.) Bernstein, J.; Videla, L.; Israel, Y. ept. Pharmacol., Univ. Toronto, Canada). *Ann. NY ad. Sci.* 242:560-572, 1974.

merous studies with rats are cited to show that ronic administration of ethanol leads to a hypertabolic condition of the liver. This hypermetalic state is produced by an increase in the activy of the sodium pump, which becomes the pacemaker r the oxidative metabolism of the hepatic cell. e increased sodium pump activity is correlated with increased activity of sodium- and potassium-activad ATPase. There also appears to be a marked decrease pump efficiency, such that more ATP is hydrolyzed to ve an equal number of ions. The permeability of the asma membrane to potassium also appears to be ineased. These 2 phenomena amplify the effect of an creased sodium- and potassium-activated ATPase on the te of cellular metabolism. Thus, chronic administraon of ethanol produces complex changes in the plasma mbrane of the liver cell. An increased activity of e sodium pump could result in an adaptive response compensate for the inhibitory action of ethanol sodium- and potassium-activated ATPase or it could a secondary effect in response to actions of ethol on other processes which might involve thyroid rmones and epinephrine. Thyroxine and epinephrine oduce a calorigenic effect in the liver that apars to be identical to that produced by long-term hanol administration.

31 THE 'CHESS BOARD' DISTRIBUTION OF GLYCOGEN IN LIVER. ARTIFACT OF FIXATION OR THE EFCT OF AN ENZYME?

(E.) Roos, R. (Anat. Inst., iv. Tubingen, Germany). *Histochem. J.* 6(5):511-1, 1974.

ver pieces (4 mm cubes) from adult SPF Spraguewley rats were fixed in Carnoy's fluid, Goland's xative, or Rossman's fixative and examined to dermine if the 'chessboard' pattern of glycogen disibution often observed after block-fixation of ver is due to the enzymatic breakdown of glycogen efore the fixative has reached the inner parts of the block) or to the plane of the section taken. Regardless of which fixation method was used, there was a central area of the section in which all the cells contained nearly equal amounts of glycogen. The area covered by this zone was inversely related to the width of the zone of localized glycogen. Periportal cells were filled with granular glycogen particles after all 3 fixation techniques, and in the region surrounding the central vein the intracellular glycogen was finely dispersed. Essentially the same glycogen distribution was found in liver perfused with *p*-chloromercuribenzoic acid which almost completely inhibits phosphorylase activity. The chessboard pattern was present in the center of surface sections, as in unperfused liver, while the central sections showed a homogeneous distribution of glycogen. The pattern appeared to be the result of the plane of sectioning passing through a region of intracellularly localized glycogen where some regions of a cell contain glycogen while other regions of other cells in the same plane do not.

9082 EFFECT OF BETA RECEPTOR BLOCKADE ON LIVER INJURY INDUCED BY CARBON TETRACHLORIDE.

(E.) Szlamka, I.; Kovach, A. G. B.; Somogyi, J.; Menyhart, J. (Semmelweis Univ. Med. Sch., Budapest, Hungary). *Acta Physiol. Acad. Sci. Hung.* 43(3):269-274, 1973.

The effect of the beta blocking agent, propranolol (2 X 10^{-2} g/100 g body weight i.p. hourly for 6 or 24 injections), was studied on the elevation of plasma free fatty acid and on fatty infiltration of the liver of rats induced by a single injection of CCl_4 (0.25 ml/100 g). Prior administration of propranolol prevented both the rise in plasma free fatty acid and hepatic fatty infiltration following CCl_4. Propanolol, however, had no effect on CCl_4-induced decreases in either the ratio of activity of bound to free lysosomal acid phosphatase or in the activity of glucose-6-phosphatase in liver homogenates. These results indicate that propranolol inhibits lipolysis in adipose tissue thus preventing the CCl_4-induced free fatty acid rise in plasma. It is concluded that the rise in plasma free fatty acid plays a permissive role in the initiation of fatty changes in the liver.

9083 ALKALINE PHOSPHATASE IN AUXILIARY LIVER TRANSPLANTATION.

(E.) Jersky, J. (Dept. Surg., Univ. Witwatersrand, Johannesburg, South Africa). *Gut* 15(8):636-643, 1974.

Auxiliary liver allografts were placed into baboons and allowed to undergo rejection during which time the incorporation of ^{14}C-leucine into alkaline phosphatase was measured in both host and donor livers by an antialkaline phosphatase antibody assay. Initial alkaline phosphatase activity was 1.4 to 4.8 King-Armstrong U/g liver. Following transplantation, serum alkaline phosphatase as well as transaminase activity increased several-fold. Although increased transaminase levels were due to release from damaged cells, increased alkaline phosphatase levels were associated with enhanced activity in both host and transplanted livers as well as in the bile from host livers. Kinetic and starch-gel electrophoretic studies confirmed that the alkaline phosphatase was of hepatic origin. Leucine injected i.v. was incorporated into alkaline phosphatase of both donor and host livers. Enhanced alkaline phosphatase synthesis continued in host livers following removal of previously transplanted donor livers. In both cases, the enhanced hepatic alkaline phosphatase synthesis was accompanied by increased biliary excretion of the enzyme.

9084 ANTIGEN OF MOUSE BILE CAPILLARIES AND CUTICLE OF INTESTINAL MUCOSA.

(E.) Khramkova, N. I.; Beloshapkina, T. D. (N. F. Gamaleya Inst. Epidemiol. Microbiol., Moscow, USSR). *Nature (Lond.).* 251(5476): 627-628, 1974.

A bile capillary-cuticular antigen (BCCA) apparently synthesized at the cell surface was identified in bile capillaries of mouse liver and in the cuticle of the intestinal mucosal epithelial cells. Gel double diffusion and immunoelectrophoresis analyses of Triton X-100 fractions of mouse liver cell ghosts and whole mouse liver cells revealed 6 antigens in all Triton fractions studied. The antigens were presumably membrane antigens. One of the antigens, called bile capillary-cuticular antigen, was regularly found in each liver Triton fraction, whereas the other 5 antigens were detected in only some of the fractions. Immunoprecipitation and indirect immunoautoradiographic studies of the distribution of BCCA in different mouse organs and in ascitic hepatoma 22-a showed BCCA to be a dominant antigenic component of liver cell and ghost fractions and to exist in considerable amounts in mouse kidney. BCCA was determined in ascitic hepatoma 22-a only by immunoautoradiography. The antigen was not detected by either method in concentrated saline extracts of mouse liver, kidney, spleen, or intestine. Indirect immunofluorescence cell localization studies of BCCA revealed a distinct bright fluorescence on the liver cell surface surrounding the bile capillaries between 2 hepatocytes. The fluorescence of bile capillaries disappeared after the absorption of monospecific antibodies to BCCA with a partially-purified BCCA-containing electrophoretic fraction. In sections of the intestine, the monospecific antibodies to BCCA stained the cuticle of the mucosal epithelial cells of villi and crypts. This distinct cuticular fluorescence was observed for the entire length of the intestine from the duodenum to the rectum. Small amounts of BCCA or an antigen with a similar determinant were also found on the plasma membrane of each liver cell. The absence of BCCA in the cytoplasm of liver cells suggested that its synthesis occurs on the cell surface.

9085 HORMONAL CONTROL OF LIVER REGENERATION.

(E.) Thrower, S.; Ord, M. G. (Dept. Biochem., Univ. Oxford, England). *Biochem. J.* 144(2): 361-369, 1974.

The effects of various drugs on ornithine decarboxylase induction, cyclic AMP production, and factors associated with DNA production were studied in partially hepatectomized male Wistar rats maintained on strict feeding and lighting schedules. Two peaks in cyclic AMP production in rat livers 2 and 12 hr after partial hepatectomy were confirmed and a 3rd was established at 22 hr which was the peak of DNA synthesis. Increases in cyclic AMP were prevented by the β-adrenergic blocking agents propranolol (10 mg/kg i.p.) and pindolol (0.5 and 1.0 mg/kg i.p.) without affecting ornithine decarboxylase induction or DNA synthesis. The α-blocking agents phenoxybenzamine (5 mg/kg i.p.) and phentolamine (10 mg/kg i.p.), given at the time of partial hepatectomy, delayed the rise in ornithine decarboxylase normally found 4 hr after surgery but did not affect DNA synthesis. The onset of DNA synthesis was delayed, however, if the α-blocking agents were given at 9-12 hr or at 18 hr. Phenoxybenzamine (5 mg/kg i.p.) did not affect the induction of ornithine decarboxylase by glucagon or growth hormone in intact rat livers but did inhibit induction by dexamethasone (0.1 and 0.5 mg/kg i.p.). The induction of ornithine decarboxylase produced by dexamethasone was inhibited by 17α-hydroxyprogesterone (50 mg/kg i.p.); this compound also blocked the induction of ornithine decarboxylase in livers of partially hepatectomized rats. The sensitivity of liver regeneration to phenoxybenzamine, phentolamine, and 17α-hydroxyprogesterone suggests that norepinephrine and glucocorticoids in rats may be implicated in inducible protein synthesis after surgery, though factors leading to the periodicity in cyclic AMP concentrations and in protein induction are not yet understood.

9086 SIMULTANEOUS HEPATIC MICROSOMAL OXIDATION OF p-NITROANISOLE AND GLUCURONIDE CONJUGATION OF p-NITROPHENOL.

(E.) Ranklin, M. R. (Coll. Med., Univ. Utah, Salt Lake City). *Biochem. Soc. Trans.* 2(5):891-894, 1974.

The simultaneous hepatic microsomal oxidation of *p*-nitroanisole and glucuronide conjugation of *p*-nitrophenol was studied in hepatic microsomal fractions from phenobarbital-pretreated rats (80 mg/kg/day for 4 days) to determine whether on-going conjugation of the product of oxidative metabolism increased the oxidative reaction *in vitro*. The rates of glucuronide conjugation of *p*-nitrophenol increased with increasing *p*-nitrophenol concentrations. There was also a decreased conjugation rate in the absence of *p*-nitroanisole. Product inhibition of *p*-nitroanisole demethylation with increasing concentrations of *p*-nitrophenol was readily apparent. The apparent disappearance of *p*-nitrophenol by glucuronide conjugation was slowed by the addition of reduced nicotinamide adenine dinucleotide phosphate (NADPH) which caused the formation of additional *p*-nitrophenol from *p*-nitroanisole. The difference between the rates of these 2 reactions (the apparent rate at which *p*-nitrophenol was being generated by oxidative dealkylation of *p*-nitroanisole) was found to be higher at all concentrations of *p*-nitrophenol than the rate observed in the absence of on-going conjugation, suggesting that on-going conjugation speeds up oxidative dealkylation. An alternative explanation became evident, however, when the experiment was performed in the absence of *p*-nitronisole. The conjugation rate of *p*-nitrophenol was nhibited on the addition of NADPH and this inhibi- ion (about 20%) was essentially independent of *p*- itrophenol concentrations. Assuming an unchanged lealkylation rate, then subtraction of the *p*-nitro- henol formation rate from its rate of removal in the resence of the nucleotide gives a conjugation rate hich when subtracted from the original rate observ- d amounts to the inhibition of conjugation caused y the reduced nucleotide. The value agrees well ith those observed for reactions in the absence of -nitroanisole, and it is concluded that on-going onjugation of the oxidative metabolism product does ot increase the oxidative reaction rate *in vitro*.

087 A ^{99m}Tc-LABELED REPLACEMENT FOR ^{131}I-ROSE BENGAL IN LIVER AND BILIARY TRACT STUDIES. *E.)* Lin, T. H.; Khentigan, A.; Winchell, H. S. Medi-Physics, Inc., Emeryville, Calif.). *J. Nucl. ed.* 15(7):613-615, 1974.

tudies on dogs and rodents have enabled the develop- ent of a ^{99m}Tc-labeled "Hepato-Biliary Scintigraphin" gent which may replace ^{131}I-rose bengal in liver and iliary tract studies. The new agent shows an ini- ial, rapid clearance from plasma by the liver, sug- esting close to a 100% hepatic extraction efficiency. he substance is excreted into the bile and engages n a liver-plasma feedback system, the net effect of hich is a rapid, near quantitative excretion of ac- ivity into the bile. Assessment of activity by cintigraphy shortly after i.v. administration of the ^{9m}Tc agent yields images comparable to those ob- ained with ^{99m}Tc-colloids except that there is no ctivity in the spleen. Subsequent serial scinti- hotos enable measurement of the regional capacity f liver to excrete the ^{99m}Tc agent into bile and herefore allows for high-resolution scintigraphic maging of gallbladder and biliary tract morphology nd function.

088 LIPID PEROXIDATION IN CHRONIC ETHANOL TREATED RATS: IN VITRO UNCOUPLING OF EROXIDATION FROM REDUCED NICOTINE ADENOSINE DINU- LEOTIDE PHOSPHATE OXIDATION. *(E.)* Koes, M.; Ward, .; Pennington, S. (Cancer Res. Ctr., Columbia, Mo.). *ipids* 9(11):899-904, 1974.

n vivo and *in vitro* experiments with chronic eth- nol-treated Holtzman rats were performed to verify hat chronic ethanol exposure induces various com- onents of the microsomal ethanol oxidizing system nd to determine if the induced microsomal system akes contribution to ethanol metabolism *in vivo* uch that lipid peroxidation might be expected to ccur. The inducibility of various intermediates f the microsomal ethanol oxidizing system was con- irmed in ethanol-treated animals. A lipid peroxi- ation (measured as malonaldehyde formation) associ- ted with ethanol metabolism by microsomal prepara- ions was also demonstrated. Alcohol dehydrogenase evels were not influenced by prior exposure to eth- nol, whereas cytochrome P-450 and reduced nicotine denosine dinucleotide phosphate (NADPH) were ele- ated (males more than females). Blood ethanol clearance studies following an intoxicating dose (6 g/kg) of ethanol to 20 female rats (5 controls, 5 controls treated with pyrazole, 5 chronic ethanol treated, and 5 chronic ethanol treated also receiving pyrazole) showed that ethanol treated animals cleared alcohol faster than controls. A comparison between control and ethanol induced animals treated with pyrazole indicated that the ethanol treated animals cleared 20% of the 8-hr reference level while controls actually had more ethanol at 16 and 24 hr. Both groups had comparable pyrazole clearing rates. *In vitro* studies with isolated microsomes in a system similar to the assay media for NADPH oxidase to test the coupling between NADPH oxidase and the generation of malonaldehyde revealed elevated levels of the aldehyde in microsomes from ethanol-treated animals along with the appearance of peroxidized materials in the solution following the addition of substrate for the NADPH oxidase enzyme. This indicated that NADPH oxidation lies near the rate determining step for the formation of peroxidized lipid in the microsomal preparations. Low concentrations of azide uncoupled the lipid peroxidation from the microsomal NADPH oxidase activity.

9089 ACTION OF HYDROCORTISONE HEMISUCCINATE ON NEW-BORN RAT LIVER EXPLANT CULTURES. *(E.)* Gueguen, C.; Guillouzo, A.; Lenoir, P.; Bourel, M. (INSERM, Pontchaillou Hosp., Rennes, France). *Biomedicine* 21(6):286-292, 1974.

SECRETION AND METABOLISM

Intestine

9170 ROLE OF ORAL INTAKE IN MAINTENANCE OF GUT MASS AND DISACCHARIDE ACTIVITY. *(E.)*

Levine, G. M.; Deren, J. J.; Steiger, E.; Zinno, R. (Philadelphia VA Hosp., Pa.). *Gastroenterology* 67(5):975-982, 1974.

To distinguish between lack of oral intake and negative nitrogen balance as the cause of small intestinal atrophy, i.v. alimentation was used to maintain 1 group of male Sprague-Dawley rats in positive nitrogen balance while they received no oral intake. A second group received an equal volume (50-60 ml/day for 1 week) of the same elemental diet *ad libitum*. All animals received in excess of 400 mg N_2/kg/day, and were in positive N_2 balance after 1 to 2 days of i.v. alimentation. After 7 days of i.v. or p.o. alimentation, the animals were sacrificed and the small intestine removed. Decreases in gut weight (22%), mucosal weight (28%), mucosal protein (35%), DNA (25%), and mucosal height were observed in i.v. alimented rats, primarily due to a decrease in these parameters in the proximal small bowel. As a result of the atrophy and hypoplasia of the proximal gut, the proximal to distal gradient of mass, protein, and DNA observed in p.o.-alimented rats was minimal in i.v.-alimented rats. I.v.-alimented rats had lower total intestinal maltase (62%), sucrase (62%), and lactase (44%), with a 46% decrease in maltase and sucrase specific activities, but without a change in lactase specific activity. Sucrase and maltase activities (specific activity and per cm) were highest in the jejunum of both groups, although they were higher in p.o.-alimented rats than in i.v.-alimented rats. Lactase activity/cm was greater in p.o.-alimented rats, reflecting the greater protein content, but without a change in specific activity.

9171 MESENTERIC VASOMOTOR EFFECTS OF VASOACTIVE INTESTINAL POLYPEPTIDE. STUDY ON PERFUSED ISOLATED CANINE JEJUNAL LOOPS. *(E.)*

Kachelhoffer, J.; Eloy, M. R.; Pousse, A.; Hohmatter, D.; Grenier, J. F. (Natl. Inst. Health Med. Res., Strasbourg, France). *Pfluegers Arch.* 352(1):37-46, 1974.

The vasomotor effect of vasoactive intestinal polypeptide (VIP) on the mesenteric vascular bed was studied in 15 dogs of both sexes in which the isolated jejunal loop was perfused *ex vivo* at normothermia, under pulsatile flow with heparinized, oxygenated and non-recirculating whole blood. VIP was administered either by intraarterial injections lasting 1 min with a flow rate of 1 ml/min or by intraarterial infusions of 10 min at the same flow rate. The 1 min injections established a dose-response relationship for injected doses between 10 ng/ml and 200 μg/ml. The results showed that VIP dilated the mesenteric vascular bed. This effect appeared dose-dependent up to concentrations of about 5 μg/ml of blood, value for which a maximal vasodepressor effect of 15 mm Hg ± 6 was reached. During long term infusions of VIP, the arterial pressure under constant flow returned toward the resting level despite continued stimulation. During the induced vasodilating period, O_2 consumption was increased. Neither propranolol (10, 50, 100, or 250 μg/ml) nor atropine (25, 100 and 250 μg atropine sulfate/ml) suppressed the vasodepressor effect of VIP. Therefore, a neuronal pathway does not seem to be involved. The experimental procedures used give no evidence for a significant physiological role of VIP in local regulation of mesenteric hemodynamics.

9172 ISOLATION OF MICROVILLUS PLASMA MEMBRANES FROM SUCKLING-RAT INTESTINE. THE INFLUENCE OF PREMATURE INDUCTION OF DIGESTIVE ENZYMES BY INJECTION OF CORTISOL ACETATE. *(E.)*

Galand, G.; Forstner, G. G. (Toronto Western Hosp., Canada). *Biochem. J.* 144(2):293-302, 1974.

To investigate membrane changes which might be involved after cortisone administration, a method for the isolation of a fraction enriched with microvillus plasma membrane was developed in suckling rats. Plasma-membrane fractions from 13-day-old control rats were compared with those from 13-day-old littermates given cortisol acetate by s.c. injection on postnatal day 10 (5.0 mg/100 g body weight), day 11 (2.5 mg/100 g) and day 12 (2.5 mg/100 g). Membrane proteins were solubilized by papain or sodium dodecyl sulfate, separated by polyacrylamide-gel electrophoresis, and assayed for enzyme activity. After cortisol injection, the activity of maltase, trehalase, sucrase, and leucyl β-naphthylamidase increased markedly, and to the same extent, in intestinal homogenates and plasma-membrane preparations. Purification and recovery of 5 marker enzymes with respect to homogenate activity, and recovery of protein, were similar for both membrane preparations, particularly after correction for non-membrane activity, which was high in suckling rats and affected by cortisol. In material released from the plasma membrane by digestion with papain, maltase protein was increased after cortisol injection at least as much as maltase activity. Sucrase activity increased at least 200-fold and this increase was associated with the appearance of a new sucrase band on polyacrylamide-gel electrophoresis. Sodium dodecylsulfate electrophoresis of plasma-membrane proteins revealed at least 4 additional macromolecules after cortisol injection. Concurrently several proteins disappeared from the plasma membrane. The added proteins appeared in general to be removed from the plasma membrane by papain, whereas the deleted proteins were in the papain-resistant fraction. Enzymic stimulation induced by cortisol acetate in the suckling-rat plasma membrane appeared to involve the addition of new proteins, rather than activation of proteins *in situ*. Deletion of proteins from the membrane during induction of hydrolytic enzymes may reflect other phenomena such as protein reorganization associated with the change in microvillus shape.

9173 EFFECT OF PROLONGED FASTING ON FATTY ACID RE-ESTERIFICATION IN RAT INTESTINAL MUCOSA. *(E.)*

Powell, G. K.; McElveen, M. A. (Univ. Texas Med. Branch, Galveston). *Biochim. Biophys. Acta* 369(1):8-15, 1974.

he effect of fasting on the absorption and transport f fat by the small intestine was studied in male oltzman rats. The animals were fasted for 60 hr; hey were then sacrificed, the intestine removed, omogenized, and analyzed for disaccharidase activity, onoacylglycerol acyltransferase, and protein. The asted rats had lost an average of 65 g (22% of ini- ial weight) and showed decreases in total intestinal ucosal protein, mucosal weight, sucrase, maltase and onoacylglycerol acyltransferase activities. Total icrosomal protein was decreased to a lesser degree n fasted rats, and total lactase activity remained nchanged. Specific activities of sucrase and mal- ase were unchanged by fasting; specific activity of actase increased. Specific activity of monoacylgly- erol acyltransferase/mg microsomal protein decreased. hen activity of this pathway was expressed per mg of ucosal protein or mucosal weight it remained unchanged n fasted animals. The results appeared consistent ith the hypothesis of decreased cell proliferation n starvation. An increase in the proportion of ounger differentiated cells in the epithelial cell opulation was also noted.

174 SOLUBLE NEUTRAL AND ACID MALTASES IN THE SUCKLING-RAT INTESTINE. *(E.)* Galand, G.; orstner, G. G. (Toronto Western Hosp., Canada). *iochem. J.* 144(2):281-292, 1974.

he separation of soluble maltase activity into 2 omponents was investigated in Wistar rats. he small intestine of suckling rats killed at 13 ays and of adult rats killed at 40 days were re- oved and homogenized and the homogenate centrifuged t 100,000 g for 1 hr to separate soluble from in- oluble membrane-bound enzymes. The supernatant rom 13-day-old rats contained 43.5% of the total ntestinal maltase activity, compared with 7.1% in he 40-day-old rats. The soluble maltase activity as separated on Sepharose 4B into 2 quantitatively qual fractions at pH 6.0, one containing a maltase ith a neutral pH optimum and the other a maltase ith an acid pH optimum. The neutral maltase was a altase-glucoamylase identical with membrane-bound altase-glucoamylase in molecular weight, heat-sen- itivity, substrate specificity, K_m for maltose and i for Tris. The soluble enzyme was induced by ortisol but the ratio of the soluble to bound en- yme fell during induction. Solubility of the neu- ral maltase was not accounted for by the action of ndogenous proteinases under the preparative condi- ions used. It is postulated that the soluble neu- ral maltase is a membrane-dissociated form of the ound enzyme and that the relation between these 2 orms is modulated by cortisol. The acid maltase enerally resembled acid maltase of liver, muscle and kidney. It was shown to a maltase-glucoamylase ith optimal activity at pH 3.0, and molecular eight of 136,000 by density-gradient centrifuga- ion. At pH 3.0 its K_m for maltose was 1.5 mM. It as inhibited by turanose and Tris but not by *p*- hloromercuribenzoate or EDTA. Some 55% of its activity was destroyed by heating at 50 C for 10 min. The acid maltase closely resembled β-glucuronidase and acid β-galactosidase in its distribution in the intestine, response to tissue homogenization in various media, and decrease in activity with cortisol treatment and weaning, indicating that it is a typical lysosomal enzyme concentrated in the ileum.

9175 DIGESTION OF PROTEIN IN SMALL AND LARGE INTESTINE OF THE PIG. *(E.)* Holmes, J. H. G.; Bayley, H. S.; Leadbeater, P. A.; Horney, F. D. (Dept. Nutr., Univ. Guelph, Canada). *Br. J. Nutr.* 32(3):479-489, 1974.

The total amounts of amino acids passing from the small intestine were compared with the amounts lost in the feces of 6 male pigs. The animals were fitted with re-entrant ileal cannulas and fed 1 kg dry matter/day, at 9 and 16 hr, with 1 of the following semi-purified diets: 1) soya-bean meal (SBM); 2) rapeseed meal (RSM); or 3) protein-free meal. Flow rates of ileal contents for 24 hr collection periods were 3135, 3127, and 1243 ml for SBM, RSM and protein-free diets, resp. Amounts of dry matter digested in the small intestine were 730, 669, and 809 g/day for SBM, RSM and protein-free diets, resp. Intake of N_2 was 32.6, 29.9, and 5.9 g/day, and the amount digested in the small intestine was 25.7, 20.2, and 1.6 g/day for SBM, RSM, and protein-free diets, resp. Amounts digested in the large intestine were 2.6, 3.7, and 0.7 g/day. Total amino acid intakes and amounts collected at the ileum and in the feces were (g/day): SBM, 177, 24, and 18; RSM, 149, 28, and 22; protein-free, 3, 9, and 12. Digestibility in the small intestine was higher for SBM than RSM for 17 of 18 amino acids, determined by ion-exchange chromatography. Greater quantities of arginine, methionine, cystine, and tyrosine were voided in the feces than passed through the ileal cannulas for pigs receiving the SBM and RSM diets. For those receiving the protein-free diet this was true for each amino acid except proline. Significant differences were found between all diets in the concentration of some amino acids in ileal and fecal amino-N, and endogenous protein secretions did not mask the differences between diets. Differences in digestibility between SBM and RSM were greater at the ileum than in the feces. Amino acid fermentation in the large intestine obscured or reduced differences between SBM and RSM. It was concluded that for SBM and RSM, 9% and 16% of nitrogen absorption, and 4% and 5% of amino acid disappearance, resp., may occur as a result of deamination and absorption in the large intestine.

9176 THE EFFECTS OF DISTENTION AND OBSTRUCTION ON THE ACCUMULATION OF FLUID IN THE LUMEN OF SMALL BOWEL OF DOGS. *(E.)* Mishra, N. K.; Appert, H. E.; Howard, J. M. (Med. Coll. Ohio, Toledo). *Ann. Surg.* 180(5):791-795, 1974.

The effects of distention and obstruction on the proximal and distal small intestine were studied in 42 dogs. Short-term distention was studied in 8 fasting dogs with jejunal ligations 10 cm below the ligament of Treitz. None of the 4 which initially had no proximal fluid showed fluid accumulation. Of the other 4 which initially did have proximal fluid, 2 showed a marked fluid accumulation during the 2 hr of distention. The other 2 showed no appreciable fluid accumulation with distention. Long-term distention was studied in 24 dogs with proximal ligations. Vomiting occurred in less than 50% and none had either proximal or distal distention after 24 to 96 hr of distention although the probability of finding fluid was directly related to the duration of distention. Long- and short-term closed loop obstruction also had little effect on fluid accumulation or distention. Distention pressures of 25 cm water tended to reduce fluid accumulation within the intestinal lumen. If these findings can be extrapolated to man, they may indicate that intraluminal fluid accumulation in the obstructed small bowel may be due to alterations in the blood supply rather than to obstruction *per se*, or to accumulated proximal small bowel fluid.

9177 LIPID COMPONENTS OF TWO DIFFERENT REGIONS OF AN INTESTINAL EPITHELIAL CELL MEMBRANE OF MOUSE. *(E.)* Kawai, K.; Fujita, M.; Nakao, M. (Tokyo Med. Dental Univ., Japan). *Biochim. Biophys. Acta* 369(2):222-233, 1974.

The microvillus membrane and the basolateral membrane of the small intestine of ICR strain mice maintained on an enriched artificial diet originally designed for the enhancement of reproduction, and of dd strain mice fed a simple growth diet, were analyzed for lipid composition. Microvillus membranes were rich in cholesterol and glycolipids but poor in phospholipids as compared with basolateral membranes and other types of plasma membranes. The total lipid content/100 mg protein was 61.5 mg in microvillus membranes and 95.2 mg in basolateral membranes. The microvillus membrane contained 16.0 mg of phospholipids and 29.0 mg of glycolipids/100 mg protein. The basolateral membrane contained 58.6 mg of phospholipids and 12.4 mg of glycolipids/100 mg protein. The molar ratio of cholesterol, phospholipid and glycolipid was 1/1/1 in microvillus membranes and 1/2.5/0.3 in basolateral membranes. Cholesterol and free fatty acids were the major neutral lipids in both membranes. Phosphatidylethanolamine and phosphatidylcholine were the major phospholipids in both membranes. Palmitic, stearic, and linoleic acids were the major fatty acid components determined in both membranes from the IRC strain. The basolateral membrane contained a little more palmitic acid and a little less stearic acid than the microvillus membrane. In both membranes the major glycolipids were ceramide monohexoside and hexosamine probably derived from globoside-type glycolipids.

9178 THE MEASUREMENT OF CELL PRODUCTION RATES IN THE CRYPTS OF LIEBERKUHN. AN EXPERIMENTAL AND CLINICAL STUDY. *(E.)* Wright, N.; Watson, A.; Morley, A.; Appleton, D.; Marks, J.; Douglas, A. (Dept. Pathol., Univ. Newcastle upon Tyne, England). *Virchows Arch.* [*Pathol. Anat.*] 364(4):311-323, 1974.

A method was developed for assessing the proliferative state in the small bowel mucosa in both animal and man, using the metaphase-arresting (stathmokinetic) properties of vincristine. In male albino Wistar rats a value for the migration of 1.78 cell positions/hr was obtained by the stathmokinetic method. This value was in agreement with a measurement of the migration rate made using tritiated thymidine. Values for the transit time through the crypt (34 hr) and for the cell production rate (39 cells/crypt/hr) were in good agreement with previously published values. A male 37-yr-old patient with a 10-yr history of dermatitis herpetiformis and a control patient were also studied by the vincristine technique. The patient with dermatitis herpetiformis had the flat mucosa of gluten-sensitive enteropathy. At 11 hr vincristine sulfate was rapidly infused i.v. in a dose of 0.045 mg/kg body weight. At 13.30 hr a Crosby capsule was fired and a mucosal biopsy obtained. The biopsies were spread flat under a stereomicroscope, fixed for 48 hr, serial paraffin sections cut at a thickness of 3 μcm and stained with hematoxylin, and the cells counted by standard methods. The migration and cell production rates were markedly increased in the flat mucosae. A hyperproductive proliferative state is therefore confirmed in the flat mucosa of untreated gluten-sensitive enteropathy. The results indicate that the vincristine technique is applicable to studies involving intestinal cell kinetics.

9179 EFFECT OF MUCIN ON THE BIOAVAILABILITY OF TETRACYCLINE FROM THE GASTRO-INTESTINAL TRACT: IN VIVO, IN VITRO CORRELATIONS. *(E.)* Barry, B. W.; Braybrooks, M. P. (Sch. Pharm., Portsmouth Polytechnic, England). *J. Pharm. Pharmacol.* 26(12): 64P-65P, 1974.

GENERAL

9195 DOES HEPATIC BLOOD FLOW DECREASE AFTER PORTAL-SYSTEMIC SHUNT? A STUDY IN THE RAT. *(E.)* Chauvaud, S.; Grange, D.; Franco, D.; Bismuth, H. (Paul Brousse Hosp., Villejuif, France). *Eur. Surg. Res.* 5(6):458-464, 1974.

Hepatic blood flow was measured by the constant BSP infusion method in 5 sham-operated Wistar rats and in 5 rats 24 hr after portacaval shunts. There were no significant differences in hepatic blood flow between the 2 groups. In sham-operated rats, hepatic blood flow was 4.6. ± 0.89 ml/min/100 g body weight and 1.37 ± 0.34 ml/min/g liver. In rats with portacaval shunts, flow was 4.04 ± 0.33 ml/min/100 g body weight and 1.32 ± 0.22 ml/min/g liver. Maintenance of a normal hepatic blood flow in shunted rats implies that hepatic arterial flow was sufficiently increased to compensate for portal blood diversion. The present results are opposed to those in the dog. Extrapolation to man of data indicating changed blood flow in shunted dogs should be reconsidered.

9196 INTERACTION OF SYSTEMIC AND LOCAL VASCULAR REGULATION OF THE INTESTINAL CIRCULATION DURING SYSTEMIC INFUSION OF NOREPINEPHRINE. *(E.)* Richardson, D. R. (Univ. Kentucky Coll. Med., Lexington). *Cardiovasc. Res.* 8(4):496-505, 1974.

Intestinal vascular dynamics during norepinephrine administration (4 μg/kg i.v.) in the cat were investigated under conditions that allowed integration of local and systemic vascular regulations. In 1 series of experiments, which involved only a portion of the small intestine, systemic regulation was excluded by placing a pressure clamp around the right carotid artery. Systemic regulation was studied by removing the pressure clamp and repeating the infusion. Results of these experiments indicated that about 60% of norepinephrine escape in the intestine during i.v. infusion was due to local regulatory adjustments and about 40% to direct and/or indirect systemic factors related to elevated blood pressure. To test the hypothesis that direct systemic adjustment was a neurogenic one operating *via* baroreceptor feed back, the norepinephrine escape response was examined before and after acute sympathetic denervation at the level of the superior mesenteric artery. This series of experiments, which involved the entire small intestine, showed that only 20% of the escape response was the result of a neurogenic mechanism. Local pressure-dependent adjustments, therefore, account for the remaining 20% of the escape not due to local autoregulatory mechanisms.

9197 METABOLISM OF ALBUMIN AND BODY FLUID COMPARTMENTS IN PROTEIN DEFICIENCY--AN EXPERIMENTAL STUDY IN THE RHESUS MONKEY. *(E.)* Deo, M. G.; Bhan, A. K.; Ramalingaswami, V. (All-India Inst. Med. Sci., New Delhi). *J. Nutr.* 104(7):858-864, 1974.

The influence of protein deficiency on the catabolism of serum albumin and body fluid compartments was investigated in 9 Rhesus monkeys tube-fed a protein-deficient diet for 9 weeks. Four control monkeys were tube-fed an isocaloric protein-rich diet for an equal length of time. In protein-deficient animals, the mean basal exchangeable albumin pool declined from 3.063 g/kg to 1.389 g/kg. The reduction was more marked in the extravascular than in the intravascular albumin pool. Protein deficiency resulted in prolongation of half-life and decreased turnover of albumin. Plasma proteins were markedly decreased in protein-deficient rats, due chiefly to a fall in plasma albumin (2.55 to 1.40 g/100 ml). Despite the reduction of serum albumin, plasma volume and extracellular fluid were not significantly altered. These findings suggest that factors other than hypoalbuminemia may be responsible for the edema of protein-calorie malnutrition.

9198 SIMILARITY OF CHRONIC COPPER TOXICITY IN RATS TO COPPER DEPOSITION OF WILSON'S DISEASE. *(E.)* Owen, Jr., C. A. (no affil.). *Mayo Clin. Proc.* 49(6):368-375, 1974.

Copper-loading was induced in male Sprague-Dawley rats by adding a 0.12% solution of cupric acid to their drinking water for periods up to 902 days. Copper concentrations in organs and excreta of these rats were compared with those reported in Wilson's disease in humans. In both conditions, very high copper concentrations occur in the liver, kidney, and urine. Little or no increase in copper was found in either condition in erythrocytes, adrenals, lungs, pancreas, bone, nails, muscle, heart, and serum. Unlike patients with Wilson's disease, copper levels were increased in rat large and small intestines, hair, bile, and feces. Specific activities of ^{67}Cu in various rat organs were studied after i.v. administration of the isotope in ionic form or incorporated into ceruloplasmin. Normal organs which accepted more ^{67}Cu from ionic copper tended to accumulate a significant amount of copper during copper loading. If the normal organ took up ceruloplasmin-^{67}Cu preferentially, little stable copper was accumulated. Organs of copper-laden rats took up less ionic ^{67}Cu than normal. In certain organs, specific ^{67}Cu activities were high initially and then decreased steadily, suggesting a relatively rapid copper turnover in such organs. This pattern occurred after injection of ionic ^{67}Cu in kidney and skin and after injection of ceruloplasmin-^{67}Cu in bone, brain, heart, and lung. Progressively increasing specific activities with ionic ^{67}Cu (brain and liver) or ceruloplasmin-^{67}Cu (skin and liver) may give a clue to the preferred forms of the metal in these organs.

9199 THE KINETICS OF RECOVERY IN IRRADIATED COLONIC MUCOSA OF THE MOUSE. *(E.)* Withers, H. R.; Mason, K. A. (M.D. Anderson Hosp. Tumor Inst., Houston, Tex.). *Cancer* 34(3)suppl.:896-903, 1974.

The acute response and kinetics of recovery of colonic mucosa to single and multiple sublethal doses of γ-rays were studied in inbred specific pathogen-free C_3Hf/Bu mice. The number of surviving cells was estimated in histological cross sections of colon at various times following irradiation by counting the number of proliferating cell colonies. The total minimal dosage was 1300 rads in single or divided doses up to 20 fractions. The colonic mucosa showed a great propensity for recovery from radiation injury. Recovery primarily was a result of sublethal injury when small numbers of large dose fractions were given. For more protracted fractionation schedules (up to 9 days), however, the sparing effect was due more to regeneration of surviving cells than to repair of sublethal injury. The rate of regeneration changed with increasingly protracted fractionation, thus resulting in nonlinear iso-effect curves, even when plotted on log coordinates. Since regeneration is so effective in sparing the colonic mucosa, the tolerance, as with other tissues, is determined by the nonproliferative components.

9200 BRIEF REPORT: RENAL AND INTESTINAL BLOOD FLOWS IN GRADED HOMORRHAGE. *(E.)* Mengoli, L. R.; Wax, S. D.; Webb, W. R. (Upstate Med. Ctr., Syracuse, N.Y.). *Circ. Shock* 1(3):239-240, 1974.

Renal and intestinal blood flows were measured in 10 mongrel anesthetized dogs subjected to graded hemorrhage. Splenectomy was performed on each animal, and square wave electromagnetic flowmeter probes were placed on the renal and superior mesenteric arteries. Systemic arterial and venous pressures as well as portal venous pressure were also monitored by appropriately placed catheters. Baseline readings were obtained for 20-45 min, and then hemorrhages of 5 cc/kg were done every 10 min until 40 cc/kg of blood had been withdrawn. Measurements of pressures and flows were made before and 5 min after each hemorrhage. Intestinal flow fell before renal flow and was depressed to 82% of baseline after the 1st hemorrhage (5cc/kg). Renal flow did not fall to a similar degree until after the 4th hemorrhage (20 cc/kg). Throughout early hypotension, intestinal flow was considerably less than renal flow; when intestinal flow had been reduced to 50% of baseline by hemorrhage totaling 15 cc/kg, renal flow was still 85% of baseline. After hemorrhage totaling 25 cc/kg, the blood pressure fell below 100 mm mercury, and the differences between renal and intestinal flow were no longer statistically significant. The possibility exists that in clinical situations where renal flow is compromised, intestinal flow may be even more severely affected and may have clinically important consequences. The lack of a precise clinical method of monitoring intestinal blood flow and function hampers further evaluation of this possibility.

9201 GASTROINTESTINAL AND MESENTERIC HEMODYNAMIC PATTERNS IN NEUROGENIC HYPERTENSIVE RABBITS. *(E.)* Alexander, N.; DeQuattro, V. (Univ. Southern California Sch. Med., Los Angeles). *Circ. Res.* 35(4): 646-651, 1974.

Blood flow patterns and vascular resistance in splanchnic tissue of rabbits with neurogenic hypertension induced by sinoaortic denervation were compared with those of normotensive sham-operated rabbits. Total splanchnic resistance was significantly higher in neurogenic hypertensive rabbits than in sham-operated animals. The magnitude of the increase varied from 34 and 35% in the cecum-appendix and ascending colon, resp., to 64 and 77% in the jejunum and stomach, resp. Blood flows were reduced 20-26% in stomach, transverse colon, decending colon, jejunum, and spleen of neurogenic hypertensive rabbits; the pancreas and the mesenteric adipose tissue had flow reductions of 27 and 42%, resp. Both groups of rabbits had an aboral flow gradient between the small and large intestines, but differences between adjacent regions were not statistically significant due to individual variation in intestinal flow patterns. Maximum duodenal flow was higher than jejunal flow in about 38% of sham-operated animals, whereas the incidence increased to 78% in hypertensive rabbits. Mean ileal flow was significantly lower than duodenal flow in hypertensive but not in sham-operated rabbits. The highly variable degree of vasoconstrictor tone within the splanchnic bed of chronic hypertensive animals reflected the net result of vascular smooth muscle response to neurogenic and local regulatory factors.

DIAGNOSTIC PROCEDURES

9212 THE USE OF MULTIPLE RADIONUCLEOTIDE IMAGING TO DIFFERENTIATE THE FOCAL INTRAHEPATIC LESION. *(E.)* Muroff, L. R.; Johnson, P. M. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(4):728-734, 1974.

A group of 35 patients with hepatic mass lesions was studied using 2 or more radiopharmaceuticals. Of the 35 patients, 18 had hepatic metastases, 9 hepatoma, 4 abscess or cyst, 3 hemangioma, and 1 hamartoma. In each case large focal intrahepatic defects were detected on the conventional colloid liver scan using 3 mC Tc^{99m}-sulfur colloid. Each patient underwent blood pool scanning with 3-5 mC In^{113m}Cl at pH 1.7 and 6 patients also received 300 μC Se^{75}-selenomethionine. Diagnostic accuracy was improved by separating the blood pool scans into 3 categories: 1, avascular or relatively hypovascular; 2, vascularity approaching or equal to that of the normal liver; and 3, more vascular than normal liver. Each category suggests at most one further study to provide specific diagnostic information. Se^{75}-selenomethionine was used to scan 6 patients with category 2 lesions. Uptake approaching or equal to that of normal liver was revealed in 4 hepatoma patients, while 2 patients with metastases had little or no uptake of the tracer. There was excellent correlation between the results of the blood pool scans and the actual vascularity as seen on angiography and tissue section. Thus, utilization of 3 radiopharmaceuticals enables greater specificity in preoperative diagnoses.

9213 LACK OF SPECIFICITY OF THE ACID PERFUSION TEST IN DUODENAL ULCER PATIENTS. *(E.)* de Moraes-Filho, Jr., J. P. P.; Bettarello, A. (Univ. Sao Paulo Sch. Med., Brazil). *Am. J. Dig. Dis.* 19(9):785-790, 1974.

The acid perfusion test was performed on 36 male patients (aged 19-59 yr) with duodenal ulcer; 22 of these patients also had a diagnosis of reflux esophagitis, while the remaining 14 had no esophageal disease. Radiologic, endoscopic, and histologic studies were performed to evaluate the state of the esophageal and gastric mucosa. Of the 22 patients with esophagitis, 15 had heartburn, 12 chronic superficial gastritis, and 13 a positive acid perfusion test. Of the 14 patients without esophagitis, 4 had heartburn, 3 chronic superficial gastritis, and 2 a positive acid perfusion test. The correlations between the presence of esophagitis and gastritis, between gastritis plus esophagitis and heartburn, and between esophagitis plus gastritis and a positive acid perfusion test were not statistically significant. The correlations between the presence of esophagitis and heartburn, between gastritis and heartburn, and between esophagitis and a positive acid test were not significant. The validity of a positive acid perfusion test as a definite diagnosis and of heartburn as a symptom characteristic of reflux esophagitis is questioned. Both are more apt to occur when both the esophageal and gastric mucosa undergo inflammatory reaction.

9214 CLINICAL EVALUATION OF PREOPERATIVE LIVER SCINTIGRAPHY IN GASTRIC CARCINOMA PATIENTS. *(E.)* Watanabe, K.; Kawahira, K.; Matsuura, K. (Kyushu Univ. Sch. Med., Fukuoka, Japan). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 121(4):720-727, 1974.

Preoperative liver scintigrams and surgical findings were compared in 137 cases of progressive gastric carcinoma and 13 cases of early gastric carcinoma. Confirmation of the presence or absence of metastases was by autopsy in 7 cases, laparotomy in 128, and clinical diagnosis in 15. Of 44 confirmed cases of liver metastases, 37 had space-occupying lesions scintigraphically. Of 106 cases without metastases, 88 had normal scintigrams. The diagnostic accuracy of liver scintigraphy in detecting liver metastases was 90.7% (136/150). No metastases were seen in the 13 patients with early gastric carcinoma. Metastases were confirmed in 28 of 50 palpable livers and scintigraphically detected in 25 of the 28. In the remaining 100 nonpalpable livers, metastases were confirmed in 16 and scintigraphically detected in 12 of the 16. Four of the 150 cases had small scintigraphically undetectable metastatic foci (< 1 cm diameter). The close correlation with surgical findings indicates that preoperative liver scintigraphy has great diagnostic value.

9215 INTESTINAL AMEBIASIS. A ROENTGEN ANALYSIS OF 19 CASES INCLUDING 2 CASE REPORTS. *(E.)* Balikian, J. P.; Uthman, S. M.; Khouri, N. F. (American Univ. Med. Ctr., Beirut, Lebanon). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):245-256, 1974.

Two case reports are presented to illustrate the value of metronidazole (500 mg 3 times/day for 1 week) in roentgen diagnosis of intestinal amebiasis. Both cases presented with an initial roentgen appearance indistinguishable from other ulcerative disease of the colon. In a 45-yr-old man; the initial roentgenograms showed spasm in the midtransverse colon, concentric and eccentric narrowings of the lumen; thumbprinting at the ends of the lesion and exaggeration of haustral markings in the intervening area; and lack of distensibility as demonstrated under air pressure. Follow-up barium enema examination after metronidazole therapy showed complete disappearance of all roentgenologic signs of disease except for minimal edema of the haustra. In a 70-yr-old man, initial barium enema study showed a long segment of the rectum concentrically narrowed with ragged superficial and deep ulcers. A penetrating ulcer was noted leading to a pericolic abscess. Posttherapy, the penetrating ulcer and the pericolic abscess were reduced in size and the remaining ulcers had disappeared. The roentgen features of these and 17 other cases of amebiasis were compared with granulomatous colitis, ulcerative colitis, and other ulcerative diseases of the colon. Amebic colitis was characterized by a multiplicity of lesions with shaggy contours and deep and superficial ulcers with a ragged appearance. Left-sided colitis was as common as right-sided colitis, and diffuse colitis was present only in the form of multiple skip lesions. Various types of nonspecific haustral and mucosal changes were noted. The annular lesion of amebomas were distinguished from carcinomas by their gradually tapering ends, fairly well-preserved mucosa, and response to antiamebic therapy.

9216 RADIOLOGIC OBSERVATIONS ON INTESTINAL AMEBASIS. *(E.)* Kolawole, T. M.; Lewis, E. A. (Univ. Coll. Hosp., Ibadan, Nigeria). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):257-265, 1974.

Radiologic examination of 8 patients with amebic colitis showed that the disease involved the cecum in all cases, the entire colon in 5, and the rectum in 4. Ulcers were observed in 5 patients and usually involved a long segment of the colon and/or rectum. The ulcers had a saw-toothed appearance initially, later becoming confluent and forming collar-stud abscesses underneath the mucosa. No definite evidence of intraperitoneal perforation was seen. Two patients presented with toxic dilation involving the transverse colon and hepatic flexure. The affected portions of the colon also showed pseudopolyposis, thumbprinting of the mucosa, and exaggeration of the haustra. One patient initially showed a lack of haustra in the descending colon (pipestem colon); 18 months later the lesion involved the entire colon and cecum, suggesting a progression of the lesion from the left half of the colon to the right. In this case the ileocecal valve was incompetent and the cecum contracted. Two cases showed multiple strictures and skip lesions involving, resp., the left half and the right half of the colon. Multiple strictures due to amebomata formation were present in 4 cases; 1 ameboma was an annular mass mimicking a carcinoma and another presented as an intussusception. In 1 patient with multiple strictures, pseudodiverticula in the midtransverse colon were more prominent after metronidazole treatment (800 mg 3 times/day for 2 weeks). Ulcers occurred in 3 patients with ameboma, 1 patient with toxic dilatation, and 1 with multiple strictures. Incompetence of the ileocecal valve was seen in all cases of total colonic involvement due to extension of the disease to the cecum and its ileocecal valve. The close similarities of radiologic changes in amebic colitis and nonspecific chronic ulcerative colitis demonstrate that a clear distinction between the 2 conditions also requires consideration of other epidemiologic, clinical, and laboratory findings.

9217 A RAPID METHOD FOR MEASUREMENT OF FRACTIONAL INTESTINAL ABSORPTION OF CALCIUM. *(E.)* Chanard, J.; Assailly, J.; Bader, C.; Funck-Bretano, J. L. (Necker Hosp., Paris, France). *J. Nucl. Med.* 15(7):588-592, 1974.

Calcium absorption was measured in 49 patients and 11 controls in less than 8 hr using only ^{47}Ca, 1st injected i.v. (5 μC) and then p.o. (10 μC) 2 hr later. Assuming that plasma disappearance of the i.v. dose was identical to that of the absorbed oral dose, it was verified that: 1) the absorption of the radioactive oral dose was achieved within 4 hr; and 2) the log curve of plasma radioactivity obtained after total absorption of the oral dose is a straight line parallel to that obtained after the i.v. dose. This corresponds to the exchangeable calcium expanding pool model. Measured fractional intestinal Ca absorption was 58.9% in controls; 90.7% in primary hyperparathyroidism; 79.3% in idiopathic hypercalciuria; 81% in Paget's disease; and 35.8% in chronic renal failure treated conservatively. Following hemodialysis, fractional intestinal Ca absorption was transiently increased to 50.6% when performed 10-12 hr after the hemodialysis run. There was no significant correlation between the fractional intestinal Ca absorption variation and variations of creatinine, bicarbonates, and protein in the plasma induced by the hemodialysis run.

GASTROINTESTINAL DISEASES

ESOPHAGUS

9233 INTRAEPITHELIAL CARCINOMA OF THE ESOPHAGUS: CASE REPORT AND CONSIDERATION TO THE SUPERFICIAL CARCINOMA OF THE ESOPHAGUS. *(E.)* Iizuka, T.; Hirata, K.; Mitomi, T.; Miwa, T.; Hirota, T.; Sano, R. (Natl. Cancer Ctr. Hosp., Tokyo, Japan). *Jap. J. Clin. Oncol.* 12(3):105-112, 1973.

An intraepithelial carcinoma of the esophagus was diagnosed in a 79-yr-old man presenting with hematemesis. X-ray examination revealed no abnormalities, but fiber esophagoscopy showed a shallow lesion in the mucous membrane. In addition, gastrocamera revealed sessile polyps on the posterior wall of the antrum. Biopsy findings were squamous cell carcinoma of the esophagus and atypical intestinal metaplasia. The patient underwent gastrotomy for removal of the sessile polyps and esophageal resection. Microscopic examination of the esophageal biopsy specimen confirmed the diagnosis of intraepithelial squamous cell carcinoma and showed no invasion below the basement membrane. The polypoid stomach tumor was an adenocarcinoma papillotubulare, but the stalk was intact. A resected esophageal carcinoma from a 51-yr-old man was also predominantly intraepithelial, but at 1 point the carcinomatous invasion extended through the lamina muscularis mucosa. In this case a papilloma was detected in the vocal cord. No lymph node metastasis from the esophageal carcinoma was seen in either case.

9234 BRONCHOGRAPHIC AND ANGIOPNEUMOGRAPHIC CHANGES ASSOCIATED WITH ESOPHAGEAL HIATUS HERNIA. AN EXPERIMENTAL STUDY IN DOGS. *(E.)* Senyk, J.; Arborelius, Jr., M.; Lilja, B.; Nylander, G. (Dept. Thoracic Surg., Univ. Lund, Sweden). *Eur. Surg. Res.* 6(2):72-78, 1974.

The effects of experimentally created esophageal hiatus hernia on bronchi and pulmonary vessels were studied in 5 mongrel dogs. Before distension neither the arterial nor the venous phase was affected by the created hiatus hernia. During distension of the gastric pouch, both the caliber of the arterial branches supplying the compressed parenchyma and the volume of the lower lobe decreased. Arteries close to the compressed parenchyma were dilated and stased. Occlusion of the posterior-basal, latero-basal or anterior-basal segments was found in 4 of the animals. A cranial dislocation and distortion of the segmental bronchi of the posterior- or latero-basal segments were noted in 2. No bronchial or vascular changes were registered in the upper part of the left lung. Some of the angiographic slow passage of contrast may have been secondary to hypoventilation and local hypoxia with active vasoconstriction. These results suggest that it is unlikely that the apical functional changes registered in 20% of the patients with hiatus hernia could be secondary to effects of the thoracic loculus *per se*. This confirms clinical findings that hiatus hernia may cause basal atelectasis and changes in the regional lung function localized to the basal parts of the lung.

9235 SURGICAL TREATMENT OF GASTROESOPHAGEAL REFLUX IN INFANTS. *(E.)* Randolph, J. G.; Lilly, J. R.; Anderson, K. D. (Dept. Surg., George Washington Univ., Washington, D.C.). *Ann. Surg.* 180(4):479-486, 1974.

A total of 31 infants under age 1 yr underwent surgery for correction of pernicious gastroesophageal reflux. The most important indications for surgery were severe growth retardation from persistent vomiting (25 patients) and recurrent aspiration pneumonia (6). Barium swallow confirmed the diagnosis of gastroesophageal reflux in all children and demonstrated a concomitant hiatus hernia in 17. Patients selected for surgery were 1st treated conservatively unless they showed significant esophagitis or had a major portion of stomach in the chest. Infants treated early in the series had Allison repairs (7 transabdominal, 2 thoracic); 20 subsequent infants had Nissen fundoplication and 2 had Boerema gastropexy. In 15 patients, significant gastric outlet obstruction required a complementary pyloroplasty. Four infants required a second surgical procedure because of recurrence; 2 of the 4 had Nissen procedures with good results, 1 following a Boerema gastropexy and 1 following an Allison repair. The other 2 patients needed revision after fundoplication. There were no operative deaths. Of 28 patients followed for 6 months to 8 1/2 yr, all have excellent nutritional status and are following normal growth curves. Study of these patients indicates the need for early diagnosis and medical or surgical therapy for all infants with major gastroesophageal reflux.

9236 UPPER OESOPHAGEAL SPHINCTER YIELD PRESSURE IN NORMAL SUBJECTS AND IN PATIENTS WITH GASTRO-OESOPHAGEAL REFLUX. *(E.)* Stanciu, C.; Bennett, J. R. (Hull Roy. Infirm., England). *Thorax* 29(4):459-462, 1974.

Upper esophageal sphincter yield pressure was measured in 26 normal subjects and in 69 patients (39 men and 30 women, aged 17-70 yr) with heartburn and acid regurgitation related to posture and meals. Of these 69, 21 had hiatus hernia and/or gastroesophageal reflux. A system of continuously perfused catheters was used for obtaining the measurements. There was no significant difference between the two groups. Perfusion of the esophagus with hydrochloric acid produced no change in sphincter pressure. The resting sphincter pressure was not related to the degree of esophagitis nor to the severity of reflux as measured by 15-hr pH recordings. These results indicate that gastroesophageal reflux is unlikely to play a major role in the etiology of pharnygeal diverticuli through the mechanism of changes in cricopharyngeal sphincter pressure. There were significant differences in sphincter pressure recorded by the 3 catheters either when their orifices were set 5 cm apart longitudinally or when they were at the same level, equidistant around the circumference of a circle. This indicates that spatial orientation of catheter tips influences the pressure recorded from a sphincter.

9237 MORTALITY FROM NEONATAL DIAPHRAGMATIC HERNIA. *(E.)* Dibbins, A. W.; Wiener, E. S. (Children's Hosp., Pittsburgh, Pa.). *J. Pediatr. Surg.* 9(5):653-662, 1974.

Arterial blood gas and acid-base patterns were studied in 20 newborns with left posterolateral diaphragmatic hernias diagnosed and operated on before age 24 hr. Three groups of infants were distinguished: (1) those with little, if any, pulmonary hypoplasia; (2) those with true bilateral pulmonary hypoplasia; and (3) those with hypoplasia of 1 lung. Group 1 corresponded to 6 survivors with normal or near normal $PaCO_2$ values, rapid expansion of the ipsilateral lung after hernia repair, and little or no postoperative right-to-left shunting. Group 2 comprised 2 nonsurvivors who failed to attain a normal $PaCO_2$ and who developed severe hypoxemia and unrelenting acidosis. Group 3, consisting of 2 survivors and 10 nonsurvivors, was characterized by initial hypercapnia and acidosis, a slowly expanding or nonexpanding ipsilateral lung, and right-to-left shunt in the postoperative period. In the latter group, both preductal and ductal shunting were seen. The clinical pattern was severe distress at birth, improvement after operation, and subsequent deterioration. In each case, onset of deterioration was identified as severe hypoxemia with shunting, usually at a preductal level, triggered by sudden pulmonary hypertension. Survival of infants with diaphragmatic hernia depends on a delicate balance between pulmonary arterial and ductal tone. Therefore, treatment should be in the direction of pharmacologic manipulation of pulmonary arterial pressure and the rate of ductal closure.

9238 SELECTIVE ARTERIOGRAPHY OF THE LEFT GASTRIC ARTERY IN THE DIFFERENTIAL DIAGNOSIS OF BENIGN STENOSIS OF THE THORACIC ESOPHAGUS. *(Cz.)* Rapant, V.; Rehulka, M.; Prasil, J. (Med. Fac., Purkinje Univ., Olomouc, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(2):136-140, 1974.

Two case reports are presented to illustrate the difficulty of differentiating between short areas of stenosis in the middle of the thoracic esophagus which complicate Barrett's esophagus and brachyesophagus secondary to reflux esophagitis. A 63-yr-old man with an 11-yr history of progressive dysphagia and no appreciable subjective symptoms was diagnosed as having brachyesophagus secondary to reflux esophagitis caused by a sliding hiatus hernia. At surgery, a short area of annular stenosis was found in an otherwise normal esophagus along with an almost undetectable axial hiatus hernia. A 51-yr-old man who had undergone gastrectomy for duodenal ulcer was suspected of having either stenosis in Barrett's esophagus or a recurrent duodenal ulcer. At surgery, the latter diagnosis was confirmed. A 57-yr-old woman complained of gallbladder symptoms, occasional vomiting, slight loss of weight, and, during the past 3 months, difficulty in swallowing which became so severe that she could only swallow liquids. Esophageal x-rays showed a small axial hiatus hernia with a short area of tubular stenosis in the middle of the thoracic esophagus with the irregular contours of a slightly dilated esophagus above the stenosis. The radiologist suspected secondary brachyesophagus and reflux esophagitis with stenosis resulting from a sliding hiatus hernia. Since these radiological findings were similar to those in another patient with granulomatous esophagitis, an unsuccessful attempt was made to perform selective arteriography of the left gastric artery to rule out secondary brachyesophagus. It was impossible to distinguish between the celiac artery and the left gastric artery and its branches from the many branches of the splenic and hepatic arteries. At surgery, secondary brachyesophagus was found along with a small axial hernia. Unfortunately, no biopsies were taken before or after surgery.

9239 SUPERSENSITIVITY TO PENTAGASTRIN IN DIFFUSE OESOPHAGEAL SPASM. *(E.)* Eckardt, V.; Weigand, H. (Dept. Med. (I), Univ. Mainz, Germany). *Gut* 15(9):706-709, 1974.

A 38-yr-old man with a 9 month history of dysphagia and substernal pain was evaluated manometrically and radiographically. Initial manometric recordings showed a lower esophageal sphincter pressure of 30 mm Hg and normal relaxation with swallowing, thus excluding the diagnosis of achalasia. Each swallow was followed by spontaneous, repetitive contractions lasting up to 30 sec. Following s.c. injection of pentagastrin (6 μg/kg), the esophagus responded in the hypersensitive fashion observed in achalasia when cholinergic agents are given. Multiple powerful, spontaneous contractions, not initiated by a swallow, appeared and mean esophageal resting pressure rose from a basal level of -2 to +8 mm Hg; lower esophageal sphincter pressure increased to 60 mm Hg. The pentagastrin effect lasted for up to 30 min during which time the patient experienced a retrosternal burning sensation. A similar hypertensive response was observed with i.v. pentagastrin (0.04-1.0 μg/kg). The pentagastrin effect was completely abolished by nitroglycerine (0.8 mg sublingual) and was inhibited by atropine (0.5 mg i.v.). Barium study following s.c. pentagastrin showed irregular localized contractions, alternating with areas of dilatation, in the lower esophagus. The so-called corkscrew appearance of the esophagus was characteristic for diffuse esophageal spasm. The inhibition of the pentagastrin effect by atropine suggests that the effect was mediated through acetylcholine release.

9240 COMBINED MYOTOMY AND HIATAL HERNIORRHAPHY. A NEW APPROACH TO ACAHALASIA. *(E.)* Peyton, M. D.; Greenfield, L. J.; Elkins, R. C. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Am. J. Surg.* 128(6):786-790, 1974.

To better assess the disease entity of achalasia and to evaluate postoperative results, patients with dysphagia and barium swallows indicative of achalasia were evaluated by esophageal function studies. Radiographic evaluation of 14 patients with dysphagia and achalasia revealed 13 with esophageal dilatation-motility disturbance, 9 with distal esophageal spasm, and 3 with esophageal reflux. There was no radiographic evidence of achalasia. Positive manometric findings in all 14 patients were discoordinated peristalsis with marked tertiary contractions plus failure of the lower esophageal sphincter (LES) to relax with barium swallowing. LES pressure averaged 17.5 mm Hg (range of 8-30 mm Hg); average length was 2.5 cm. The standard acid reflux test (SART) revealed esophageal reflux in 7 patients, an incidence of 50% compared with the 21% incidence by radiography. Eight patients were treated with Heller esophagomyotomy and Belsey Mark IV hiatus herniorrhaphy. Postoperative studies showed reversal of LES spasm and obstruction, and abatement of radiographic reflux. Although the SART revealed persistence of reflux in 2 patients, clinical resolution of symptoms and weight gain reflected successful management.

9241 EVALUATION OF CURRENT OPERATIONS FOR THE PREVENTION OF GASTROESOPHAGEAL REFLUX.

(E.) DeMeester, T. R.; Johnson, L. F.; Kent, A. H. (Tripler Army Med. Ctr., Honolulu, Hawaii). *Ann. Surg.* 180(4):511-525, 1974.

A prospective, randomized study was done on 45 patients to evaluate the effectiveness of the Hill, Nissen, and Belsey antireflux procedures. All patients had symptoms of gastroesophageal reflux unresponsive to medical therapy, a positive standard acid reflux test, esophagitis (38/45), or a positive Bernstein test (7/45). Esophageal symptomatic, radiographic, manometric, and pH (standard acid reflux test and 24-hr monitoring) evaluation was done pre- and postsurgery (average of 154 days). All procedures improved the symptoms of pyrosis, but improvement was best after the Nissen repair. Only the Nissen procedure gave complete protection against gastroesophageal reflux, as shown by the standard acid reflux test and 24-hr esophageal pH monitoring, a sensitive measurement of frequency and duration of reflux. Recurrence of hiatus hernia in 1 patient with a Hill repair and in 3 with a Belsey repair was associated with recurrence of reflux on pH testing. The Nissen and Belsey repairs increased distal esophageal sphincter pressure significantly more than the Hill repair. Sphincter length and dynamics remained unchanged. The Nissen procedure placed significantly more of the manometric sphincter below the respiratory inversion point in the positive pressure environment of the stomach. Esophageal length was increased by the Nissen and Hill repairs, which may account for the high incidence of temporary dysphagia following these repairs. Despite the dysphagia and inability of 50% of 15 patients with Nissen repairs to vomit, the procedure is the method of choice for surgical therapy of gastroesophageal reflux. It produces a competent cardioesophageal sphincter by increasing its resting pressure and improving its response to an increase in intragastric pressure. Morbidity was low after the Nissen repair (complications occurred in 2 patients but in only 1 case were related to the repair technique). For patients without complications, the average hospital stay after the Nissen repair was 11 days. Follow-up studies 283-696 days after surgery showed no recurrence of reflux in 3 patients with Nissen repairs. In contrast, 1 of 3 with a Hill repair and 2 of 3 with a Belsey repair had a late recurrence of reflux.

9242 A CONTROLLED TRIAL OF METOCLOPRAMIDE IN REFLUX OESOPHAGITIS.

(E.) Paull, A.; Grant, A. K. (Queen Elizabeth Hosp., Adelaide, Australia). *Med. J. Aust.* 2(17):627-629, 1974.

A double-blind controlled trial was instituted to assess the symptomatic benefit of oral metoclopramide in patients with gastroesophageal reflux. A group of 31 patients entered the 6-week trial. Of these 31, 16 (9 men, 7 women, aged 30-76 yr) were given placebo tablets, and the remaining 15 (7 men, 8 women, aged 26-72 yr) received metoclopramide tablets (10 mg). One tablet was administered 1/2 hr before meals three times/day and one on retiring. Of the 15 who received metoclopramide, 10 experienced significant and sustained improvement. Of the 16 receiving placebo, 7 also derived sustained improvement. There was therefore no significant statistical difference between the 2 groups, although the trend favored metoclopramide. Side effects were infrequent. Of the patients receiving metoclopramide, 2 noted drowsiness and dizziness, but similar symptoms were documented in 2 receiving placebo. One person on metoclopramide experienced recurrent masseter spasm and tongue dystonia for the first 4 days, but on continuation of the tablets, these symptoms disappeared. The improvement of 7 patients while using placebo tablets suggests that personal attention to the individual sufferer with esophageal reflux may be an important factor in affording relief of symptoms.

9243 FUNCTIONAL DISORDERS OF THE OESOPHAGUS.

STOMACH

9249 THE ANATOMICAL LOCALIZATION OF CARCINOMA OF THE STOMACH. A COMPARISON OF RADIOLOGICAL SERIES IN JAMAICAN AND AUSTRALIAN PATIENTS. *(E.)* Bateson, E. M. (Darwin Hosp., Australia). *Med. J. Aust.* 1(17):647-650, 1974.

A comparison was carried out of the anatomical location of cancer of the stomach as demonstrated by barium meal x-ray examinations of 185 patients in Western Australia (35% female, average age 69.0 yr) and 177 patients in Jamaica (34% female, average age 61.5 yr). Of those cancers which could be localized in the Jamaica series, 82% were in the antrum, 12% in the body and 6% in the fundus. Corresponding figures for the Western Australia series were 44%, 40%, and 16%, resp. Due to the small number of carcinomas in the fundus, the stomach was re-divided for the purposes of this study into 2 parts, proximal (fundus and body) and distal (antrum). No significance of location in relation to sex was noted. The Jamaica series showed a preponderance of distal growth at all ages, whereas the Western Australia series had a preponderance of proximal growths at all ages. Both series showed an increasing incidence of distal carcinoma with increasing age. The high incidence of cancer of the antrum of the stomach in Jamaica and in other developing countries of the world suggests a common factor which may be related to dietary deficiencies common in such countries, namely caloric, protein, vitamin A, calcium and riboflavin deficiencies.

9250 FEULGEN—CYTOPHOTOMETRIC STUDIES OF GASTRIC MUCOSAL SMEARS IN MALIGNANT AND BENIGN DISEASES OF THE STOMACH. *(E.)* Wiendl, H. J.; Schwabe, M.; Becker, G.; Kowatsch, J. (Surg. Clin., Univ. Munich, Germany). *Acta Cytol. (Baltimore)* 18(3):222-230, 1974.

Cytophotometric DNA determinations were made of endoscopically removed brush smears from benign and malignant stomach diseases (32 carcinomas, 1 reticulosarcoma, 31 benign ulcers, 22 pronounced inflammatory conditions, and 8 polyps). DNA peak formation in normal stomach mucosa was in the diploid region. All malignant tumors showed a definite increase in mean DNA content, broad scattering of determined values, and a shift of the DNA peak to the aneuploid region. However, smears from ulcers, inflammatory conditions (including 12 cases of intestinal metaplasia), and polyps also showed elevated DNA and aneuploidy. From 26-58% of all cells lay in the intertriploid-tetraploid region. The data indicate that stomach diseases that might become cancerous cannot be differentiated on the basis of DNA determinations. As a prescreening method, automated assessment of DNA distribution in stomach smear preparations is highly problematic.

9251 SPECIES DIFFERENCES IN SUSCEPTIBILITY TO THE GASTRO-ULCEROGENIC ACTION OF ANTI-INFLAMMATORY AGENTS. *(E.)* Wilhelmi, G. (Pharmaceut. Div., Ciba-Geigy Ltd., Basel, Switzerland). *Pharmacology* 11(4):220-230, 1974.

Phenylbutazone in 2 doses of 100 mg/kg produced gastric ulceration in various strains of rats treated p.o. and in quail, axolotl, and crucian carp treated i.m. or i.p. Results in mice were negative following p.o. administration. Treatment of rats, guinea pigs, and mice with several different doses of phenylbutazone, oxyphenbutazone, indomethacin, and flufenamic acid showed that the rat stomach was the most sensitive to the ulcerogenic effects of the 4 anti-inflammatory agents (all administered p.o.). Dosages were 2 X 1 to 2 X 100 mg/kg for indomethacin and 2 X 25 to 2 X 400 mg/kg for the other agents. In mice and guinea pigs, ulceration occurred only in response to the higher doses. Like phenylbutazone, flufenamic acid was mildly ulcerogenic in guinea pigs and mice but markedly so in rats. Oxyphenbutazone had a very slight ulcerogenic effect in mice and guinea pigs and a more pronounced effect in rats. Indomethacin had a mild effect in guinea pigs but was highly ulcerogenic in rats and mice. The margin between the ulcerogenic and lethal doses of phenylbutazone, oxyphenbutazone, and flufenamic acid was wide in the rats and narrow in the guinea pig and the mouse. With indomethacin, the margin was wide in the mouse and narrow in the other species. The anti-inflammatory activity of the 4 preparations against acute paw edema differed in the same species. In the guinea pig, all 4 preparations showed a favorable therapeutic ratio, i.e., relation between anti-inflammatory and ulcerogenic activity; in the mouse and the rat, no consistent relation was demonstrable. In most cases, however, anti-inflammatory activity at a given dose level did not parallel gastro-ulcerogenic activity.

9252 CARCINOEMBRYONIC ANTIGEN AND BLOOD GROUP SUBSTANCES IN CARCINOMAS OF THE STOMACH AND COLON. *(E.)* Denk, H.; Tappeiner, G.; Davidovits, A.; Eckerstorfer, R.; Holzner, J. H. (Univ. Vienna Sch. Med., Austria). *J. Natl. Cancer Inst.* 53(4):933-942, 1974.

Carcinoembryonic antigen (CEA) of the digestive system and blood group substances (BG) were studied in gastric and colon carcinomas by indirect immunofluorescence and mixed-cell agglutination reaction, resp. In contrast to CEA, no positive correlation between BG and the differentiation of the tumor was found. In adenocarcinomas of the colon and stomach, CEA and BG, if present simultaneously, showed different localizations. CEA was detected on the lumen-oriented surface of the tumor cells, whereas BG were distributed over the whole cell. Anaplastic carcinomas were either CEA negative or contained only minute amounts of CEA, but expressed BG in roughly the same percentage as well-differentiated carcinomas. Signet-ring cells consistently positive for CEA localized in the cytoplasm were mostly BG negative. The BG activity in gastric and colon cancers was ethanol sensitive. Only in some predominantly well-differentiated adenocarcinomas did BG resist to some degree the ethanol treatment. Anti-BG serum did not react with CEA in this system, which indicates either that the morphologic methods were too insensitive to detect cross-reactivity or that sites on CEA responsible for the cross-reactions with BG-A antiserum observed *in vitro* were uncovered during isolation and purification. In some frozen sections of gastric and colon carcinomas, the BG activity detected was not compatible with the BG of the patient.

9253 STUDIES OF INTESTINAL METAPLASIA IN THE GASTRIC MUCOSA BY DETECTION OF DISACCHARIDASES WITH "TES-TAPE." *(E.)* Kawachi, T.; Kogure, K.; Tanaka, N.; Tokunaga, A.; Sugimura, T.; Koyama, Y.; Kanasurgi, K.; Hirota, T.; Sano, R. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan). *J. Natl. Cancer Inst.* 53(1):19-30, 1974.

The range and intensity of intestinal metaplasia in the gastric mucosa were estimated by visualizing the activities of disaccharidases with Tes-Tape. Specimens were obtained by gastrectomy of 111 patients with gastric carcinoma, 2 with gastric sarcoma, 13 with gastric ulcer, and 8 with duodenal ulcer. In both stomach cancer and ulcer, the incidence and intensity of sucrase and maltase activities were high in the antrum and lowest along the greater curvature, especially on the oral side. The area giving a positive reaction for maltase was wider than that for sucrase, and the color reaction for maltase was stronger than that for sucrase in the area where both reactions were positive. Trehalase activity was detected in some cases. The trehalase reaction was closely associated with the area where the alkaline phosphatase reaction was positive and where Paneth's cells were observed histologically. The area giving a sucrase reaction coincided well with the area where appearance of intestinalization was proved histologically by the presence of goblet cells, but was not related to presence of Paneth's cells.

9254 MALABSORPTION SECONDARY TO ANTRAL GASTRIN-CELL HYPERPLASIA. *(E.)* DiMagno, E. P.; Go, V. L. W. (Mayo Clin., Rochester, Minn.). *Mayo Clin. Proc.* 49(10):727-738, 1974.

A 48 yr old man with hypergastrinemia and antral cell hyperplasia in the absence of a pancreatic tumor is described. He originally presented with malabsorption and subsequently developed a peptic ulcer in the 3rd portion of the duodenum, had hypergastrinemia which increased 4-fold after a test meal, and had elevated levels of antral tissue gastrin. Total gastrectomy was performed. In the intervening 2 yr period, the patient has had normal fasting serum gastrin levels and no diarrhea or loss of weight. The serum gastrin response to feeding, the increased gastrin content of the antrum, the absence of a gastrinoma, and the short clinical course (7 months from onset of disease to total gastrectomy) characterize antral cell hyperplasia and differentiate it from the classic Zollinger-Ellison syndrome with gastrinoma. However, as in Zollinger-Ellison syndrome with gastrinoma, malabsorption in this patient with antral cell hyperplasia was due to gastric hypersecretion inactivating pancreatic lipase and causing excessive dilution of small intestinal contents. The thyroid-binding globulin deficiency in this patient was probably an incidental finding and is not known to have been reported as occurring with Zollinger-Ellison syndrome or with any other endocrine disease.

9255 MALLORY-WEISS SYNDROME. A REAPPRAISAL. *(E.)* Watts, H. D.; Admirand, W. H. (San Francisco Gen. Hosp., Calif.). *JAMA* 230(12):1674-1675, 1974.

A review of 840 patients treated for upper gastrointestinal hemorrhage at a large metropolitan hospital over a 7-yr period revealed the Mallory-Weiss lesion as the bleeding site in 36 (4.5%). The 36 patients included 31 men and 5 women, aged 29-71 yr. Diagnosis was established by endoscopy (29 patients) or surgery (2), or both (5). Mucosal tears were located in the distal esophagus, proximal stomach, and astride the cardioesophageal junction with equal frequency. All patients had significant melena or hematemesis or both on admission. Hiatus hernia was present in 53% of the patients, gastritis in 54%, and esophagitis in 17%. Only 7 patients required surgery and only 22 required transfusion (average 1200 ml of blood). The only death in the series occurred because of postoperative complications unrelated to the basic lesion. The data suggest that the Mallory-Weiss syndrome has a wider and more benign clinical spectrum than has been reported previously.

9256 THE ROLE OF CHOLESTYRAMINE IN THE PREVENTION OF STRESS ULCERS. *(E.)* Zike, W. L.; Safaie-Shirazi, S.; Denbesten, L. (Univ. Iowa

Coll. Med., Iowa City). *J. Surg. Res.* 17(5):315-319, 1974.

The role of cholestyramine in the prevention of bile salt-induced stress ulceration during hemorrhagic shock, and reduction of ionic movement across the gastric mucosal barrier was investigated in mongrel dogs. The dogs were bled to a mean arterial blood pressure of 40-45 mm Hg and maintained at this pressure for 4 1/2 hr. The duodenum had been occluded with a noncrushing clamp proximal to the common bile duct to prevent any regurgitiation of bile or duodenal chyme into the stomach. During hemorrhagic shock 8 dogs were injected intragastrically with 100 cm^3 of a solution containing HCl (100 mEq/liter), taurocholic acid (15 mM/liter), and polyethylene glycol (2 mg/ml). Another 8 dogs received 100 ml of a solution containing the same additives followed by cholestyramine (4 g). None of the cholestyramine-treated dogs had gastric mucosal lesions at autopsy, whereas all dogs which received HCl and bile acid had severe mucosal alterations typical of stress ulcers. The lesions were most prominent in the fundus but were also present in the antrum. Cholestyramine significantly reduced back diffusion of H^+ across the gastric mucosal barrier (-0.73 ± 0.30 mEq/liter/30 min *versus* -3.58 ± 0.30 mEq/liter/30 min). Cl^- efflux and Na^+ and K^+ influx were also decreased by cholestyramine. On the basis of its ability to prevent a break in the canine gastric mucosal barrier and to reduce H^+ ion loss, a clinical trial of cholestyramine in humans is warranted.

9257 ENHANCING EFFECT OF CLAMPING OF THE PORTAL VEIN ON THE EFFECTIVENESS OF ANTITUMOR AGENTS AGAINST ABDOMINAL TUMOR GROWTH. *(E.)* Kaibara, N.; Wakasugi, K.; Kumashiro, R.; Inokuchi, K. (Fac. Med., Kyushu Univ., Fukuoka, Japan). *Gann* 65(2):119-122, 1974.

The effect of clamping of the portal vein on the tissue levels of various chemotherapeutic agents in various abdominal organs was studied in female Donryu rats bearing a transplantable anaplastic pulmonary carcinoma. Anesthetized animals received an i.v. injection *via* the tail vein of either mitomycin-C (20 mg/kg), bleomycin (45 mg/kg) or 5-fluorouracil after which the portal vein was clamped for 10 min. Under these conditions, the levels of all 3 drugs in stomach and small intestine were twice those in controls. Liver, abdominal muscle and serum levels were unaffected. Direct examination of tumor size 12 days after treatment showed that tumor growth was markedly suppressed in animals which had received mitomycin-C followed by portal vein clamping; the effects of the other 2 drugs were not studied in this manner. The number of foci of lymphatic metastases and of peritoneal dissemination were especially decreased following clamping. Thus, simultaneous i.v. injection of antitumor agents with clamping of the portal vein may induce higher tissue levels and enhance the suppressive effect on tumor growth.

9258 GASTRIC XANTHELASMA: ENDOSCOPIC RECOGNITION. *(E.)* Javdan, P.; Pitman, E. R.; Schwartz, I. S. (City Hosp. Ctr., Elmhurst, N.Y.). *Gastroenterology* 67(5):1006-1010, 1974.

A 36 yr old male presented with intermittent upper abdominal pain which had lasted for about 4 yr. Pain was located in the epigastrium without radiation and had no relation to meals. Nausea was frequent, but no vomiting. Stool examination disclosed ova of *Ascaris lumbricoides*, *Trichuris trichuria*, and hookworm. Piperazine and thiabenazole were given after which stools were negative for parasites, and eosinophils in the peripheral blood decreased from 8% to 1%. Still the patient suffered epigastric pain. A gastrointestinal series suggested prepyloric gastric ulcers. Six weeks after an ulcer regimen, the gastrointestinal series was normal but the patient still suffered epigastric discomfort. An esophagogastroduodenoscopy was performed. The esophagus was normal. A yellow sessile nodule approximately 5 mm in diameter was noted in the prepyloric area. Two other flat or slightly elevated yellowish-pink lesions were noted 2 to 3 cm distal to the first. The hematoxylin and eosin-stained section revealed pyloric gastric mucosa. The lamina propria between the glands was occupied by large ovoid to polygonal histiocytes having an abundant, finely vacuolated, cytoplasm staining light with eosin. No identifiable periodic acid Schiff-stainable material was noted, thus indicating the absence of a mucopolysaccharide component. The foam cell nuclei were regular, round to ovoid, and occupied a small portion of the cell area. No mitoses were observed. By oil red O technique, the cytoplasmic vacuoles were shown to represent a stainable lipid appearing as bright orange-red droplets. It is suggested that while the significance of the lesion is questionable a more careful search endoscopically and pathologically of gastrectomy specimens and stomachs at autopsy will reveal gastric xanthelasma in higher percentages of patients than has been recognized thus far.

Peptic Ulcers

9281 LEARNED CONTROL OF GASTRIC ACID SECRETIONS IN ULCER PATIENTS. *(E.)* Welgan, P. R. (Milwaukee County Hosp., Wisc.). *Psychosom. Med.* 36(5):411-419, 1974.

If individuals could learn visceral and glandular responses and were thus able to control the blood flow and motility in the stomach, factors contributing to conditions such as peptic ulcer might be controlled. An attempt was made to train 10 peptic ulcer patients (8 men and 2 women, aged 35-60 yr) to increase the pH of gastric acid secretions. In the 1st experiment, in the presence of pH feedback, the 10 subjects showed significant increases in pH of gastric acid secretions, while acid concentration and volume of secretions significantly declined. When feedback was subsequently withheld, no significant changes appeared in these measures. A 2nd study was then initiated to test whether initial changes following the basal period were experimental effects. The 10 subjects were divided into 2 groups, 1 receiving no feedback after basal condition, the 2nd group receiving feedback after basal condition. Results showed that significant increases in pH and decreases in acid concentration and volume occurred only after the onset of pH feedback. This preliminary work suggests that gastric acid secretion may be altered and controlled with the appropriate feedback.

9282 INVESTIGATIONS ON THE RELATIONSHIP BETWEEN MAXIMAL ACID OUTPUT AND PARIETAL CELLS IN GASTRIC MUCOSAL BIOPSIES WITH SPECIAL REFERENCE TO DUODENAL ULCER. *(E.)* Schmidt-Wilcke, H. A.; Haake, U.; Riecken, E. O. (Med. Univ. Clin., Marburg/Lahn, Germany). *Acta Hepatogastroenterol.* 21(4):297-302, 1974.

Male patients (aged 36-76 yr) with duodenal ulcer, chronic atrophic gastritis, and controls without gastrointestinal disease were examined with respect to the relation of their maximal acid output and parietal cell density in gastric mucosal biopsies. Maximal acid output was measured using the pentagastrin (1.5 μg/kg/hr) infusion test. Parietal cells were marked histochemically in fresh frozen sections by means of their SDH-activity. Controls and duodenal ulcer patients showed a biphasic course with a peak during the 3rd collection period after the start of infusion, and a slight decrease of 10% (maximum) during the following periods. In contrast, a delayed increase of acid secretion was noted in patients with superficial and chronic atrophic gastritis. This could indicate functional impairment of the parietal cells in conditions of gastritis. In comparing mucosal appearance with parietal cells marked by the SDH-reactivity, a marked difference between the parietal cell density of the duodenal ulcer patients and controls was not easily seen. This is in contrast to the patients with superficial and chronic atrophic gastritis. There seems to be an overall reduction of the parietal cells in superficial gastritis, while in atrophic gastritis the diminution is much more pronounced and irregular in distribution. In chronic atrophic gastritis patients, a significant decrease in total mucosal thickness and glandular mucosal thickness was found. The mucosa of duodenal ulcer patients, however, showed a marked increase of these parameters; correspondingly, the mucosa of these patients showed a considerable increase in parietal cell density. In patients with superficial and, in particular, chronic atrophic gastritis, the parietal cells were significantly diminished. Findings also indicate that there is not only hypertrophy of the mucosa, but also hyperplasia of the parietal cells. There was a linear relation of parietal cell density to the maximal acid output.

9283 AETIOLOGY OF DUODENAL ULCER: AN INVESTIGATION INTO THE BUFFERING ACTION AND EFFECT ON PEPSIN OF BRAN AND UNREFINED CARBOHYDRATE FOODS. *(E.)* Tovey, F. I. (Basingstoke Dist. Hosp., Mysore City, India). *Postgrad. Med. J.* 50(589):683-688, 1974.

Staple carbohydrate foods from various populated areas of the world were investigated for their buffering action and for their effect on pepsin activity. Their effect on gastric secretion was compared with the effect of milk and of antacids. Results indicate that rice bran and some unrefined grains (ragi, maize, whole-meal wheat) buffer more acid than the refined food-stuffs (polished rice, cassave or white flour). The buffering effect is most marked over a pH range of 1.5-3. Digestion by pepsin increased the buffering effect of food substances, more so in those which are less refined. Using 37.5 mEq as the average 1 hr maximal acid output in a duodenal ulcer patient, the following quantities of food would be needed to buffer it to pH 7.4: polished rice, 1250 g; unpolished rice, 357 g; ragi, 417 g. Gastric acid secretion was measured in 17 duodenal ulcer patients in response to food substances. Using the convention of free and total acid, the total acid concentration was higher in the presence of bran, milk and alkalies, but ragi and cholam gave similar levels to polished rice. Free acid levels were similar in pattern, except for milk powder which had a more powerful and prolonged buffering effect with lower levels of free acid. Measurement of the effect of food substances on pepsin activity did not suggest the presence of any powerful pepsin inhibitor in rice bran or wheat bran or in any of the unrefined grains tested. These results do not support the theory that the loss of buffer in the preparation or refinement of the staple carbohydrate food is the whole explanation of any protective effect of unrefined foods in peptic ulcer. Although rice bran, wheat bran, ragi, and maize do have a greater buffer content than do refined carbohydrate foods such as polished rice, white flour and cassave, the former group are also antral stimulants, resulting in an increased acid output in the stomach. Only when the buffering effect exceeds the stimulus to greater acid output will there be a fall in acid concentration.

9284 PSYCHIATRIC DISTURBANCE AND POSTVAGOTOMY DIARRHOEA. *(E.)* Johnstone, E. C.; Allan, J. G.; Geraghty, B. P.; Russell, R. I. (Southern Gen. Hosp., Glasgow, Scotland). *J. Psychosom. Res.* 18(3):205-208, 1974.

Postvagotomy diarrhea occurred in 14 of 28 patients who had undergone vagotomy and drainage operations for duodenal ulcers. To determine if the diarrhea was related to psychological factors, the Goldberg Standardized Psychiatric Interview and a self rating scale, the Middlesex Hospital Questionnaire, were administered to postvagotomy patients with and without diarrhea and to patients with nonspecific dyspepsia (12), peptic ulcer (13), and chronic blood diseases (14). Postvagotomy patients with diarrhea had significantly higher Goldberg scores than patients with peptic ulcer and chronic blood disorder. On the Middlesex Hospital Questionnaire, the postvagotomy patients with diarrhea scored significantly higher than patients with chronic blood diseases. The absence of any significant difference between postvagotomy patients with and without diarrhea indicates that the diarrhea was not secondary to psychological factors.

9285 BLOOD SUPPLY TO THE HUMAN GASTRODUODENAL MUCOSA WITH SPECIAL REFERENCE TO ULCER-BEARING AREAS. *(E.)* Piasecki, C. (Roy. Free Hosp. Sch. Med., London, England). *J. Anat.* 118(2):295-335, 1974.

The intramural arteries of the healthy human stomach and duodenum were studied postmortem by injection and cleaning of specimens from 13 adults, 4 fetuses, 1 stillbirth, and 1 neonate. While previous authors have noted only poverty of the vasculature of the lesser curvature as a whole, the present findings show a quantitative decrease in number and caliber of anastomoses from cardiac to pyloric parts. In the submucous plexus the degree of anastomosis in the cardiac area is similar to that on the mid-anterior and posterior walls and is significantly greater than in the pyloric region. The diminuation may be gradual or may occur at the halfway point. In the duodenum the plexus is poorest close to the pylorus and increased distally. The supraduodenal artery is not an end artery. However, only a small proportion of the flow in its parent trunks can pass through its anastomoses on the anterior wall, assuming that flow is proportion to the 4th power of the radius in the postmortem state. In general, mucosal arteries arose from the submucous plexus. However, a few single mucosal arteries arose extramurally, pierced all the muscle, and made little or no communication with the submucous plexus. In the stomach they occurred on both curvatures but were most common in the pyloric 1/2 of the lesser curvature including the incisura. These vessels, when present at the incisural region, might be constricted by prolonged peristaltic waves that stand still in this region, thus inducing chronic gastric ulceration. In the duodenum, such mucosal arteries were found only around the circumference of the 1st inch of the organ. A logarithmic relation was established between postmortem caliber of the mucosal arteries and the area of mucosa they supply. There was a single population of mucosal arteries. As a rule there was no anastomosis between mucosal arteries and their branches, with micromanipulation indicating that apparent anastomoses were due to overlapping of vessels. No single arterio-venous anastomosis was seen, possibly because specimens were not injected before 24 hr postmortem.

9286 MULTIPLE BENIGN GASTRIC ULCERS: A CLINICAL AND GASTROSCOPIC STUDY. *(E.)* Dagradi, A. E.; Falkner, R. E.; Lee, E. R. (Long Beach VA Hosp., Calif.). *Am. J. Gastroenterol.* 62(1):36-45, 1974.

Gastroscopic examination of 119 men (aged 22-89 yr) with benign gastric ulcer demonstrated multiple ulcers in 36 (30%) and solitary ulcer in 83 (70%). X-rays had been negative in 11 patients with multiple ulcers and in 31 with solitary lesions. The incidence of ingestion of ulcerogenic drugs, primarily salicylates, in relation to onset of symptoms was 92% for patients with multiple ulcers and 38% for those with solitary lesions. In an aged-matched group of patients, the incidence of salicylate ingestion close to time of hospitalization was 16.5%. Upper gastrointestinal bleeding occurred in 75% of patients with multiple ulcers and in 48% with solitary ulcer. However, the degree of blood loss was greater for patients with solitary lesions, 75% of whom required transfusion compared with 55% with multiple ulcers. Multiple ulcers were 0.5-3.0 cm in diameter and solitary ulcers from 0.5-4.0 cm. In all cases, the ulcers were largest when first encountered and subsequently exhibited a progressive reduction in size and/or number. The majority of multiple ulcers (66%) disappeared during the first 2 weeks compared with healing of 20% of solitary lesions in the same period. In 12 patients in whom healing of all but 1 of multiple ulcers occurred within 2 weeks, the remaining ulcer followed the same course of healing as that of solitary ulcers. Superficial and atrophic gastritis was present to the same extent in both groups. Approximately 1/2 of patients tested (15 with multiple ulcers and 39 with solitary) had significantly low basal and histalog-stimulated gastric secretions. The demonstration of plural lesions and the apparent etiologic relation to salicylate ingestion are the only characteristics which would permit consideration of multiple benign ulcers as a clinical entity.

9287 GASTRIC ACID SECRETION AND RISK OF RECURRENCE OF DUODENAL ULCER WITHIN SIX TO EIGHT YEARS AFTER TRUNCAL VAGOTOMY AND DRAINAGE. *(E.)* Kronborg, O. (Bispebjerg Hosp., Copenhagen, Denmark). *Gut* 15(9):714-719, 1974.

The value of insulin and augmented histamine tests in predicting recurrence of duodenal ulcer within 6-8 yr after truncal vagotomy and drainage was assessed in a series of 500 consecutively and electively operated patients. Criteria of recurrence were established by a discriminative analysis of gastric acid secretion parameters. Recurrence was predicted with a probability of about 75% in patients with dyspepsia, the ratio between recurrence and dyspeptic nonrecurrences being 1:1. The discriminatory ability of the insulin test was no better than that of the postoperative histamine test. Men with a preoperative peak acid output (PAO) greater than 46.1 mEq/hr after histamine had a 21% risk of recurrence; women with a PAO greater than 41.5 mEq/hr had a risk of 28%. Below these levels the risk was 5 and 1%, resp., demonstrating that recurrence after vagotomy is related to the number of parietal cells before vagotomy. Duodenal ulcer patients with a high number of parietal cells should be treated with vagotomy and antrectomy.

9288 LYSOLECITHIN: A FACTOR IN THE PATHOGENEIS OF GASTRIC ULCERATION? *(E.)* Johnson, A. G.; McDermott, S. J. (Charing Cross Hosp. Med. Sch., London, England). *Gut* 15(9):710-713, 1974.

Lysolecithin concentrations were measured in intermittent samples of night gastric juice from 10 patients with gastric ulcers, 10 with duodenal ulcers, and in 5 normal controls. In the gastric ulcer patients, the mean of the peak concentration (444 μg/ml) and mean of concentrations in all samples (100 μg/ml) were significantly higher than in controls (34 μg/ml and 18 μg/ml, resp.) Duodenal ulcer patients had mean values between the gastric ulcer and control groups: 5 patients with peak values less than 100 μg/ml resembled control patients in the mean of peak samples and mean of all samples, while 5 patients with peak values greater than 100 μg/ml had values approaching those of the gastric ulcer patients. Four patients with recurrent gastric ulcers after surgery had higher lysolecithin concentrations than those found in primary gastric ulcer. Of 2 subjects retested after 6 months, a control patient had similar results on both occasions but a patient with recurrence of gastric ulcer showed an increase in peak values (from 430-920 μg/ml) and mean values (from 290-359 μg/ml). Lysolecithin levels in gastric ulcer patients were as high as those found to damage the dog's mucosal barrier. It is concluded that reflux of lysolecithin is as important, or more important, than reflux of bile salts in breaking the mucosal barrier and therefore in the etiology of gastric ulcer.

9289 CHRONIC DISEASE IN FORMER COLLEGE STUDENTS. XIII. EARLY PRECURSORS OF PEPTIC ULCER. *(E.)* Paffenbarger, Jr., R. S.; Wing, A. L.; Hyde, R. T. (Univ. California Sch. Public Hlth., Berkeley). *Am. J. Epidemiol.* 100(4):307-315, 1974.

A total of 487 male former students (1.8% of 26,954 questionnaire respondents) reported doctor-diagnosed peptic ulcer with onset between college case-taking and questionnaire response 16-50 yr later. One-half of the ulcers were duodenal, 1/10 gastric, and the rest unspecified as to type. Peptic ulcer incidence rates were computed in relation to traits and medical events recorded at college-case taking. Factors that predisposed to an increased incidence of peptic ulcer in later life were coffee and soft drink consumption; tobacco smoking habits; lower systolic blood pressure; less participation in physical activity and varsity sports; and history of indigestion or diarrhea. Paired combinations of these characteristics in youth additively augmented the risk of subsequent peptic ulcer. Neither tea nor alcohol consumption in college influenced the incidence of peptic ulcer, but milk consumption was inversely related. None of 10 self-assessed personality traits or a similar battery of doctor-assessed psychological traits distinguished students who later developed peptic ulcer. Habitual coffee consumption in college emerged as the best predictor of subsequent peptic ulcer, while milk consumption identified those most likely to remain free of peptic ulcers. With coffee consumption, ulcer incidence rates increased from 17.7/1000 for abstainers to 31.7 for consumers of 2 or more cups/day, a 79% differential. Milk drinkers had an ulcer incidence of 16.4/1000 compared with 30.3/1000 for nondrinkers, a 46% reduction. In paired combination with high-risk characteristics, the suggestion of a protective effect from drinking milk was substantial.

SMALL INTESTINE

9306 CLINICAL AND LABORATORY STUDY OF POSTVAGOTOMY DIARRHOEA. *(E.)* Browning, G. G.; Buchan, K. A.; Mackay, C. (Western Infirm., Glasgow, Scotland). *Gut* 15(8):644-653, 1974.

A group of 32 patients who had diarrhea following bilateral truncal vagotomy for chronic duodenal ulcer were studied. In 16 patients (13 men and 3 women, mean age 44.6 yr) this was combined with a Heineke-Mikulicz pyloroplasty and in the other 16 patients (11 men and 5 women, mean age 45.8 yr) with a retrocolic gastroenterostomy. Surgery had been performed an average of 4.1 yr previously. In 8 patients (25%) the diarrhea was a daily occurrence, whereas in the other 24 it was episodic in nature. An additional group of 24 patients who also had elective surgery for chronic duodenal ulceration but who did not experience diarrhea was studied. Each of these 24 patients had had a bilateral truncal vagotomy and in 12 this was combined with a Heineke-Mikulicz pyloroplasty and in the other 12 with a retrocolic gastroenterostomy; surgery had been performed an average of 1.5 yr earlier. The incidence of bacterial colonization of the upper small intestine was no different in the 2 groups, although patients with a gastroenterostomy had a significantly higher incidence than those with a pyloroplasty. There was a higher incidence of anaerobic colonization in patients with diarrhea, but the difference was not statistically significant. Colonization was associated with lower levels of gastric acid secretion. Although 13 patients with diarrhea had an abnormal fecal fat excretion, no correlation could be found between this and the severity of the diarrhea or bacterial colonization, either with an anaerobic or a coliform type flora. No small intestinal mucosal abnormality was noted in patients with diarrhea, their mean hematological and serum biochemistry values were normal, and the body weights of these individuals was similar to that before operation. Abnormal hematological values were noted in 2 patients with diarrhea 5 yr after vagotomy and gastroenterostomy in association with anaerobic colonization of the upper small intestine. As the incidence of hematological abnormalities after gastric surgery increases with time, colonized patients might merit particularly close clinical observation.

9307 ENTEROKINASE IN CONTAMINATED SMALL-BOWEL SYNDROME. *(E.)* Rutgeerts, L.; Mainguet, P.; Tytgat, G.; Eggermont, E. (Dept. Pediatr., Univ. Louvain, Belgium). *Digestion* 10(4/5):249-254, 1974

Enterokinase, trypsin, and amylase were measured in duodenal and jejunal contents of 6 patients with bacterial overgrowth in the proximal small intestine. The patients included 1 man and 2 women with multiple diverticula of the proximal small bowel, 1 man with eosinophilic enteritis, and 2 men with chronic intestinal pseudo-obstruction. Activities of all 3 enzymes were significantly decreased in the duodenal content; in the proximal jejunal fluid only enterokinase was significantly reduced. In both the duodenal and proximal jejunal, enterokinase activity was less than 1/3 of normal. In 2 patients with Crohn's disease, duodenal enterokinase and trypsin activities were normal. In contrast, enterokinase activity was absent in the dilated ileum proximal to the obstructing lesions of Crohn's disease. The simultaneous occurrence of unmeasurable enterokinase and measurable trypsin activities in patients with proximal bacterial overgrowth would indicate enough enterokinase remained to initiate activation of trypsinogen. However, in situations of massive proximal overgrowth with extensive mucosal damage, mucosal and luminal enterokinase could be low enough to impair protein digestion despite sufficient output of pancreatic proenzymes.

9308 LUMINAL DISTENSION AS A POSSIBLE CONSEQUENCE OF EXPERIMENTAL INTESTINAL PERFUSION. *(E.)* Wingate, D.; Hyams, A.; Phillips, S. (Mayo Clin., Rochester, Minn.). *Gut* 15(9):728-732, 1974.

In a quantitative analysis of the clinical effects of incomplete intestinal perfusate recovery, proximal jejunal segments of healthy subjects were perfused by a double-lumen technique with glucose electrolyte solutions containing 0, 2.5, 5.0, and 10.0 mM/liter concentrations of glycocholic acid, glycochenodeoxycholic acid, and glycodeoxycholic acid. The subjects received 4 consecutive 90-min perfusions, each perfusion containing 1 of the bile acid concentrations. Distress occurred only during perfusions with 5 and 10 mM/liter dihydroxy bile acids, i.e., at concentrations that arrest absorption or provoked net secretion. The clinical effects of these perfusions were associated with poor recovery of secretogenic perfusates. Analysis of volume changes demonstrated that secretogenic perfusions may generate substantial fluid volumes in the lumen of the small intestine. Such volumes can cause discomfort in healthy subjects and may possibly be hazardous in the presence of intestinal disease. When solutions are perfused into the small intestine in conditions associated with net fluid secretion, care is required to avoid excess perfusion rates and to ensure adequate perfusate recovery.

9309 THE SMALL INTESTINE IN DERMATITIS HERPETIFORMIS. *(E.)* Fry, L.; Sea, P. P.; Harper, P. G.; Hoffbrand, A. V.; McMinn, R. M. (St. Mary's Hosp., London, England). *J. Clin. Pathol.* 27(10): 817-824, 1974.

Both the numbers and the site of the lymphocytes in the epithelium were studied in small intestinal biopsies from 43 patients with dermatitis herpetiformis (21 men and 22 women, aged 23-76 yr) to determine the relation of lymphocytes to the gluten-sensitive enteropathy associated with this disease. The diagnosis of dermatitis herpetiformis was made on clinical and histological criteria and on the presence of IgA deposits in the uninvolved skin. The macroscopic appearance of the intestinal biopsy was flat in 13, convoluted in 10, leaves only in 8, and leaves in 12. Small intestinal biopsies from 20 patients (7 men and 13 women, aged 22-73 yr) without dermatitis herpetiformis or gastrointestinal disorder showed leaves only in 3 and fingers and leaves in 17. The mean total lymphocyte counts/1000 epithelial cells in the control group was 159 ± SE 13. In the patients with dermatitis herpetiformis the mean lymphocyte count/1000 epithelial cells was 464 ± SE 27 for the flat biopsies, 365 ± SE 59 for the convoluted biopsies, 535 ± SE 39 for the leaves only biopsies, and 301 ± SE 31 for the fingers and leaves biopsies. The counts for all 4 groups were significantly greater than in the control group. Three of the 43 patients with dermatitis herpetiformis had lymphocyte counts below 200/1000 epithelial cells: 4 controls had counts greater than 200 but none above 300. In the control group the mean count for lymphocytes in the basal position of the intestinal epithelium was 79 ± SE 8; in the dermatitis herpetiformis group the count was 89 ± SE 11 for flat biopsies, 93 ± SE 12 for convoluted biopsies, 121 ± SE 18 for the leaves only biopsies, and 98 + SE 13 for the fingers and leaves. However, the mean lymphocyte count in the perinuclear position was 81 ± SE 7 for controls, 362 ± SE 23 for the flat dermatitis herpetiformis biopsies, 251 ± SE 46 for the convoluted specimens, 402 ± SE 23 for the leaves only specimens, and 195 ± SE 25 for the fingers and leaves biopsies. The mean lymphocyte count for the supranuclear position was 0.55 ± SE 0.22 for control biopsies, 13.7 + SE 2.3 for the flat dermatitis herpetiformis biopsies, 20.0 ± SE 6.9 for the convoluted biopsies, 14.5 ± SE 3.3 for the leaves only biopsies, and 8.3 ± 2.6 for the fingers and leaves biopsies. Thus, in gluten-sensitive enteropathy the increase in lymphocytes in the intestinal epithelium is in the perinuclear and supranuclear position.

SMALL INTESTINE

Malabsorption

326 MALABSORPTION IN OVERLAND TRAVELLERS TO INDIA. *(E.)* Tomkins, A. M.; James, W. P. .; Walters, J. H.; Cole, A. C. E. (London Sch. Hyg. rop. Med., England). *Br. Med. J.* 3(5927):380-384, 974.

alabsorption occurred in 28 men and 6 women (mean age, 25 yr) after brief periods of overland travel to India. Symptoms included diarrhea, abdominal distension, and weight loss. Investigation revealed steatorrhea in 29 (fecal fat, mean 15.2 g/day), xylose malabsorption in 33 (5-hr urinary excretion after a 25-g p.o. load, mean 2.2 g), and vitamin B_{12} malabsorption in 11 of 12 (2.9% of a 1-mg dose excreted).

Serum folate and vitamin B_{12} levels were lower in those with protracted diarrhea, but no anemia developed. Under the dissecting microscope, jejunal biopsies showed leaves, ridges, and convolutions. Light microscopy revealed shortened villi with infiltrations of lamina propria and epithelium by plasma cells and lymphocytes. Tropical sprue in these patients may have resulted from folate deficiency caused by methods of food preparation known to deplete the diet of folate. Once tropical sprue is established, further folate depletion can occur as dietary folate is consumed by bacteria, fails to be hydrolyzed from the polyglutamate form, and is excessively excreted in the feces.

9327 SPRUE IN THE MIDDLE EAST: FIVE CASE REPORTS. *(E.)* Haeney, M. R.; Montgomery, R. D.; Schneider, R. (East Birmingham Hosp., England). *Gut* 15(5):377-386, 1974.

Five patients (4 men, 1 woman, aged 20-64 yr) are presented whose symptoms of unexplained malabsorption began during a period of residence in the Middle East or Mediterranean areas. On the basis of malabsorption of 2 or more unrelated substances, the clinical features of the 5 cases were indistinguishable from tropical sprue as seen in the accepted endemic zones. Anemia was not present in this series due to the short duration of symptoms (3-18 months) and the good nutritional stores of the patients. A normal FIGLU excretion in the 2 patients tested was also a reflection of the short symptomatic period. Variations in serum folate and in malabsorption of fat, xylose, or vitamin B_{12} appeared related to the duration of the disorder as well as to individual nutritional reserves. Bacterial overgrowth in the jejunum was seen in 2 cases and in all 5 cases the morphological appearance of the jejunal biopsy conformed to the spectrum of characteristic but nonspecific changes in tropical sprue.

9328 DIARRHEA ASSOCIATED WITH MEDULLARY CARCINOMA OF THE THYROID: STUDIES OF INTESTINAL FUNCTION IN A PATIENT. *(E.)* Isaacs, P.; Whittaker, S. M.; Turnberg, L. A. (Manchester Roy. Infirm., England). *Gastroenterology* 67(3):521-526, 1974.

Investigation of small intestinal function in a 40-yr-old man with diarrhea associated with a medullary carcinoma of the thyroid indicated that jejunal transport of electrolytes, mucosal permeability, and intestinal transit were all normal. The ileum, however, was unable to absorb Na^+ and Cl^- against a concentration gradient, had an abnormal mucosal permeability, and had an abnormally rapid mean transit time, These disorders of ileal function could clearly account for the diarrhea. Prostaglandin secretion by the tumor did not appear responsible for the intestinal abnormalities since plasma prostaglandin levels were normal on 3 occasions and slightly elevated on 1. Indomethacin (50 mg 3 times/day for 8 weeks), a known inhibitor of prostaglandin synthesis, failed to influence the diarrhea in this patient.

9329 MALABSORPTION OF VITAMIN B_{12} AFTER VAGOTOMY. *(E.)* Streeter, A. M.; Duraiappah, B.; Boyle, R., O'Neill, B. J.; Phelis, M. T. (Repatriation Gen. Hosp., Concord, New South Wales, Australia). *Am. J. Surg.* 128(3):340-343, 1974.

Absorption of ^{57}Co vitamin B_{12} bound to chicken serum (0.8-1.0 μg p.o.) was studied in 20 patients more than 5 yr after they had undergone vagotomy and a drainage procedure. All 12 patients with successful vagotomy showed malabsorption of the bound ^{57}Co B_{12} (urinary excretion below 0.5%). Seven of the 8 patients with unsuccessful vagotomy had normal absorption (urinary excretion above 0.5%). Plasma levels after administration of bound ^{57}Co B_{12} showed a similar pattern although there was more overlap between groups.
The amount of ^{57}Co B_{12} absorbed by the postvagotomy patients was roughly proportional to their gastric output measured before and after insulin stimulation. Hydrochloric acid was shown to release bound ^{57}Co B_{12} *in vitro*, the proportion released ranging from 40% at low acid concentrations to 20% at concentrations of 40-200 mEq/liter. The release of bound B_{12} by acid *in vitro* and the rough correlation between gastric acidity and bound vitamin B_{12} by acid *in vitro* indicate that acidity may be a critical factor in the release of vitamin B_{12} from food stores prior to absorption. Thus, any disease or surgical procedure that substantially reduces gastric acid may reduce absorption of protein-bound vitamin B_{12}. The test of absorption of bound vitamin B_{12} may be a convenient substitute for the Hollander insulin test.

333 EPITHELIAL PROLIFERATION AND MORPHOGENESIS OF HYPERPLASTIC ADENOMATOUS AND VILLOUS
'OLYPS OF THE HUMAN COLON. *(E.)* Wiebecke, B.;
randts, A.; Eder, M. (Inst. Pathol., Univ. Munich,
ermany). *Virchows Arch.* [*Pathol. Anat. Histol.*]
64(1):35-49, 1974.

he morphogenetic mechanisms in the development of
olonic polyps were deduced from the structure of the
ucous membrane and the distribution of epithelial
roliferation in various layers of the mucosa. The
tructure of the mucosa was demonstrated by graphical-
erspective partial reconstruction; the parameter of
roliferation activity was the mitotic index. The
aximum of the mitotic index in normal and hyper-
lastic mucous membranes was close to the base, where-
s in villous and adenomatous polyps it was unequi-
ocally shifted to the membrane surface. Mucosal
eight and the size of the proliferation zone in-
reased progressively in the sequence from normal
ucosa through hyperplastic polyps to adenomatous
nd villous polyps. Graphical reconstruction showed
hat hyperplastic polyps develop by lengthening and
nlargement of the crypts due to increased supply of
ells from an extended but normally located regen-
ration zone. Adenomatous and villous polyps are
ased on a loss of epithelial differentiation and
he shifting of proliferation activity to the upper
ayers of the mucosa. The increased epithelial
roliferation close to the surface induces a secon-
ary stroma proliferation that results in glandular
ivision and horizontal expansion of adenomatous
olyps. In villous polyps, a predominantly vertical
rowth with villus formation takes place. Most
olyps are probably villous, adenomatous, or of mixed
ype from their inception.

334 PHASE 1 and PHASE 2 PROLIFERATIVE LESIONS OF COLONIC EPITHELIAL CELLS IN DISEASES
EADING TO COLONIC CANCER. *(E.)* Lipkin, M. (Mem.
loan-Kettering Cancer Ctr., New York, N.Y.). *Cancer*
4(3)suppl.:878-888, 1974.

he proliferation of colonic epithelial cells during
eoplastic transformation was studied in 3 groups:
1) patients who develop either isolated polyps,
illous adenomas, or carcinomas; (2) patients with
amilial polyposis; and (3) mice given the carcino-
en 1,2-dimethylhydrazine. Colonic epithelial cells
n man begin to develop some of the characteristics
f malignant cells while they still appear normal
n conventional morphological examination. The cells
ass through specific phases during which they ex-
ress increasingly abnormal proliferative character-
stics. As a Phase 1 proliferative lesion develops,
olonic epithelial cells do not repress DNA synthe-
is during their maturation, and begin to develop an
nhanced ability to proliferate. The overall kinet-
cs of cell proliferation remain normal, without a
et retention or accumulation of cells in the mucosa.
s a Phase 2 proliferative lesion forms, the cells
egin to develop properties that enable them to be
etained in the mucosa in increasing numbers. The
verall kinetics of cell proliferation become ab-
ormal, and net retention and accumulation of cells
egin to be observed. These changes are accompanied by differentiation-specific molecular errors, resulting in the abnormal persistence of metabolic pathways leading to enhanced DNA synthesis. These proliferative cellular lesions arise in hereditary familial polyposis in man, in individuals in the general population who develop isolated colonic neoplasms, and in rodents after a chemical carcinogen is given, suggesting that they are major steps on a final common molecular pathway leading to malignant transformation. Their expression is accelerated in familial polyposis. The proliferative lesions and increasingly severe degrees of cellular atypia can be screened in familial polyposis. The utility of the screening procedure is being studied.

9335 EOSINOPHILIC ARGENTAFFIN CELLS IN THE HUMAN APPENDIX. *(E.)* Millikin, P. D. (Peoria-Tazewell Pathol. Group, Ill.). *Arch. Pathol.* 98(6): 393-395, 1974.

One hundred normal appendices, removed incidental to other abdominal surgery, and 24 appendices from patients with acute appendicitis were examined for the presence of eosinophilic argentaffin cells. The normal specimens were removed from 19 male and 81 female patients (9 to 82 yr) and the appendicitis specimens from 12 male and 12 female patients (7 to 83 yr). The specimens were brightly eosinophilic after being fixed for 6-9 hr in formaldehyde solution and stained with hematoxylin and acidified eosin. The eosinophilic cells were photographed, destained, and then restained by one of three different enterochromaffin methods (silver stain, ferricyanide stain, and a diazo method using fast red B), giving a positive reaction in every case. These cells are a normal component of the appendiceal crypts (100/100 normal cases) but fewer of them were found in cases of acute appendicitis (16/24 cases). There were no differences according to age or sex.

9336 INTESTINAL COMPLICATIONS IN RHEUMATOID ARTERITIS AND THEIR RELATIONSHIP TO CORTICOSTEROID THERAPY. *(E.)* Prillaman, W. W.; Hurst, D. C.; Ball, G. V.; Bennett, J. C. (Univ. Alabama Med. Ctr., Birmingham). *J. Chronic Dis.* 27(9/10): 475-481, 1974.

Case reports of 1488 patients with rheumatoid arthritis were reviewed for intestinal arteritis as a complication of rheumatoid arteritis and for a possible relation between the complication and previous steroid therapy. Rheumatoid arteritis was found in 254 patients, 144 of whom had received steroids. Intestinal arteritis was described in 43 patients (31 men, 6 women, sex unknown in 6 cases). Site of the lesion was the small bowel alone in 12 patients, colon alone in 12, both in 7, and unknown in 12. Of the 43 patients, 31 had received steroids immediately prior to onset of clinical arteritis, 9 had not, and in 3 steroid therapy was not described. Most (84%) of the steroid-treated patients had received maintenance doses (> 7.5 mg prednisone or equivalent dose of another steroid). The steroid and non-steroid treated groups did not differ in age of onset, duration, or staging of arthritis. Further comparison between the 2 groups showed no significant difference in occurrence of intestinal complications, histology of the lesions, or number of lesions/patient as a cause of death. From these observations it appears that steroid therapy neither causes nor aggravates arteritis in rheumatoid disease.

Ulcerative Colitis

9360 BILIARY TRACT CARCINOMA ASSOCIATED WITH ULCERATIVE COLITIS. *(E.)* Ritchie, J. K.; Allan, R. N.; Macartney, J.; Thompson, H.; Hawley, P. R.; Cooke, W. T. (St. Mark's Hosp., London, England). *Q. J. Med.* 43(170):263-279, 1974.

A biliary tract tumor was documented in 15 patients (9 men and 6 women) with ulcerative colitis. Most patients had both a long history of colitis and total involvement of the colon. Seven of the patients were managed medically for the colitis and in 8 total proctocolectomy was carried out. In the latter group, the tumor was diagnosed 3-13 yr after surgery. The site of the tumor was the gallbladder in 1 patient, intrahepatic bile duct in 1, and extrahepatic bile duct in 13. In 8 cases the biliary tract tumor was found at postmortem and in 4 cases there was operative evidence of the diagnosis together with biopsy data. No surgical treatment of the tumor was possible in 3 of the 4 cases. Three patients underwent excision of the tumor and 2 underwent palliative bypass surgery; the longest survival in operated patients was 19 months. Histological study revealed that the tumors were adenocarcinomas of varying degrees of differentiation. Mucin secretion was a variable feature. A scirrhous reaction in the stroma was frequently seen at the site of the primary growth in bile ducts. It is suggested that biliary tract tumors are approximately 10 times more frequent in patients with ulcerative colitis than in the general population.

PANCREAS

9364 CYTODIAGNOSIS OF PANCREATIC MALIGNANT TUMORS BY ASPIRATION, UNDER DIRECT VISION, USING A DUODENAL FIBERSCOPE. *(E.)* Endo, Y.; Morii, T.; Tamura, H.; Oruda, S. (Ctr. Adult Dis., Osaka, Japan). *Gastroenterology* 67(5):944-951, 1974.

Duodenal endoscopic examinations with cytodiagnosis by direct aspiration and retrograde pancreatography were performed on 160 patients with suspected pancreatic disease, particularly malignant tumors. Positive results were obtained cytologically in 22 cases with no false-positive results, i.e. in 79% of the 29 cases of malignant pancreatic tumors confirmed at operation or autopsy. The 22 cases consisted of 15 of 16 cases of cancer of the pancreatic head with duodenal invasion, 4 of 6 cases of cancer of the pancreatic head without duodenal invasion, 2 of 6 cases of cancer of the body and tail of the pancreas, and the 1 case of cancer of the ductal spreading type. Aspiration of pure pancreatic juice collected from the pancreatic duct gave a positive diagnosis in 11 of 14 cases. Of the 3 negative cases, 1 cancer of the pancreatic head with duodenal invasion was confirmed histologically as an islet cell carcinoma. In the other 2 cases, cancer of the pancreatic tail was located at a distance from the papillary orifice. Diagnosis by endoscopy alone was relatively successful only in cases of cancer of the pancreatic head with duodenal invasion (9 of 16 cases). Retrograde pancreatography with a duodenal fiberscope gave a definite diagnosis in 12 cases: 5 cases of cancer of the pancreatic head with duodenal invasion, 3 cases without duodenal invasion, and 4 cases of cancer of the body and tail of the pancreas. It is concluded that cytodiagnosis is the most reliable method available for diagnosis of intrapancreatic cancer.

9365 HYPOTONIC DUODENOGRAPHY IN SUSPECTED PANCREATIC DISEASE.

(E.) Shirley, D. V. (Hammersmith Hosp., London, England). *Br. J. Radiol.* 47(560):437-443, 1974.

On completion of secretion testing, hypotonic duodenography was carried out in 60 patients with suspected pancreatic disease. Of the 46 patients with a final diagnosis of no pancreatic disease, 42 had normal duodenograms. Findings unrelated to pancreatic disease included 1 lymphoma of the duodenum, 1 large diverticulum of the 4th part, and 1 diverticulum plus pancreatic calcification. Only 3 of 7 cases of proven chronic pancreatitis were diagnosed by hypotonic duodenography. The only diverticula arising from the 2nd part of the duodenum were found in patients (2) with chronic pancreatitis. Six of 7 cases of carcinoma of the pancreas were diagnosed preoperatively by duodenography; in all 6 cases the carcinoma was in the region of the head. The 7th patient had a carcinoma of the body of the pancreas at laparotomy, but the duodenogram appeared normal. Carcinoma was wrongly suggested by duodenograms in 1 patient with no pancreatic disease and 1 with chronic pancreatitis. Carcinoma of the pancreas was present in 5 of 12 patients presenting with obstructive jaundice.

9366 RAPID GASTRIC EMPTYING OF FATTY MEALS IN PANCREATIC INSUFFICIENCY.

(E.) Long, W. B.; Weiss, J. B. (Philadelphia Gen. Hosp., Pa.). *Gastroenterology* 67(5):920-925, 1974.

To determine whether maldigestion leads to aberrations in gastric emptying of liquid fatty meals, gastric emptying was studied in 7 patients with pancreatic insufficiency (6 men and 1 woman, aged 29-55 yr) and in 10 normal controls (6 men and 4 women, aged 21-55 yr). The patients had chronic calcific pancreatitis, steatorrhea, and diabetes mellitus. Gastric emptying of meals was determined by serial dilutions of phenol red (750 mg) given by gastric tube. One hr after ingestion, 36.8 ± 5.1% of fatty meals remained in the stomach of normal subjects, while only 3.9 ± 1.1% remained in the stomach of patients. The amount remaining at 30 min in normal subjects also exceeded that in patients (75.8 ± 6.9 *versus* 27.8 ± 4.6%). These differences were significant. A heat-labile factor in dessiccated porcine pancreas (Viokase, six 0.3 g tablets mixed with the meal) significantly retarded emptying of fatty meals in patients (40.3 ± 6.3% of the mean remained at 60 min). Viokase increased gastric pH 60 min after a fatty meal from a mean of 4.6 to 5.2. It did not alter emptying rate of 5% glucose in water meals. It is concluded that abnormally rapid emptying of fatty liquid meals in patients with pancreatic insufficiency is probably due to maldigestion. Enzyme replacement improves digestion and this in turn inhibits gastric emptying.

9367 PANCREATIC SECRETION OF CALCIUM IN HEALTHY SUBJECTS AND VARIOUS DISEASES OF THE PANCREAS.

(E.) Gullo, L.; Sarles, H.; de Barros Mott, C.; Tiscornia, O.; Pauli, A. M.; Pastor, J. (Res. Unit Dig. Dis., INSERM, Marseille, France). *Rend. Gastroenterol.* 6(1):35-44, 1974.

Calcium secretion in duodenal juice was measured before and after secretin (1 U/kg) and pancreozymin (3 U/kg) administration in 36 normal subjects and 132 patients with pancreatic or nonpancreatic disease. Patients who had undergone cholecystectomy had a smaller increase in calcium concentration than normal subjects following secretin and pancreozymin injection. In patients with various diseases of the digestive tract but no pancreatic involvement, the calcium concentration did not differ from that in controls. In contrast, patients with disease of the pancreas (chronic pancreatitis with or without calcification, acute pancreatitis, diabetes, or cancer) had increased calcium concentrations compared with controls. The increase was seen both in the basal secretion and in the samples collected after injection of secretin and pancreozymin. The rise was not related to enzyme (amylase) or bicarbonate secretion. The absence of a marked rise in calcium levels in the postcholecystectomy patients indicates that increased concentrations after secretin and pancreozymin administration are mainly due to calcium-rich gallbladder bile entering the duodenum. Results for the patients with pancreatic disease suggest that measurement of duodenal juice calcium concentration could be a useful diagnostic tool. The concentration before and after secretin and pancreozymin may accurately reflect the presence of pathological pancreatic lesions, regardless of their nature. Since calcium concentration increased to the same extent in pancreatic diseases with and without calcification, the increased concentration is not in itself a cause of calcified stones in the pancreatic ducts.

PANCREAS

Pancreatitis

9376 SECRETORY PATTERNS IN MINIMAL PANCREATIC INFLAMMATORY PATHOLOGIES. *(E.)* Dreiling, D. A.; Bordalo, O. (Mount Sinai Sch. Med., New York, N.Y.). *Med. Chir. Dig.* 2(5):269-274, 1973.

Standard secretin test data and augmented secretin test data were analyzed for patients with alcoholic pancreatitis, biliary tract pancreatitis, and for alcoholics without signs of pancreatitis or cirrhosis. In patients with chronic pancreatitis, maximum bicarbonate concentration and 80-min bicarbonate secretion were significantly below the lower limit of normal statistical ranges. In contrast, 80-min average flows for alcoholic and biliary tract pancreatitis were well above the lower limit of normal. Alcoholics without pancreatitis or cirrhosis showed average high flow, normal but below average maximum bicarbonate concentrations, and normal but above average rate of bicarbonate secretion. These findings represent pancreatic hypersecretion as observed in alcoholic cirrhosis. Frequency distribution curves showed a bimodal or 2 population distribution for flow in both alcoholic and biliary tract chronic pancreatitis and a unimodal or normal distribution of values for maximum bicarbonate concentration in both groups. In each group, a significant number of patients had values in the hypersecretory ranges. The findings suggest that the initial post-secretin secretory pattern of minimal pancreatic inflammatory pathology is hypersecretion resulting from ductular reduplication and hypertrophy. With chronic inflammation and fibrosis, volume and bicarbonate concentration decline. A final stage of low flow, low bicarbonate, and low enzyme secretion corresponds to the more advanced pathologies of fibrosis, atrophy, and calcification.

LIVER AND BILIARY TRACT

9387 PATHOLOGY AND MORPHOLOGY OF PRIMARY LIVER CANCER ASSOCIATED WITH OPISTHORCHIASIS. *(Rus.)* Glumov, V. Ia.; Kotrikov, V. V.; Tretiakov, N. A. (Semipalatinsk Med. Inst., USSR). *Vopr. Onkol.* 20(9):46-50, 1974.

Postmortem morphological studies of 19 males and 25 females with primary hepatic cancer revealed chronic opisthorchiasis invasion in 42 cases. Greater incidence of opisthorchiasis-associated cancer was observed in males aged 50 and females aged 60. Liver sections showed numerous pale-gray tumorous nodules. Bile ducts were irregularly swollen with evidence of cholangiectasis containing mucus, epithelial desquamatae, helminths and bile. In 7 cases hepatic cancer was associated with pronounced cirrhotic changes. Jaundice was observed in 14 cases. Histological examination revealed cholangiocellular adenocarcinoma in 35 cases which might be the result of a pathological regeneration of bile duct epithelium. In 9 cases hepatocellular cancer developed with cirrhosis and diffuse hepatic fibrosis.

9388 HEPATIC PORPHYRIAS: CYTOCHEMICAL AND ULTRASTRUCTURAL STUDIES OF LIVER IN ACUTE INTERMITTENT PORPHYRIA AND PORPHYRIA CUTANEA TARDA. *(E.)* Biempica, L; Kosower, N.; Ma, M. H.; Goldfischer, S. (Albert Einstein Coll. Med., Bronx, N.Y.). *Arch. Pathol.* 98(5):336-343, 1974.

Case reports are presented for 11 patients with hepatic porphyrias, 7 with porphyria cutanea tarda and 4 with acute intermittent porphyria. Needle biopsies of liver tissue were obtained in 10 patients, and in case 11 an autopsy was performed. Cytochemical and ultrastructural studies showed similar subcellular alterations in both porphyrias, but histologically the damage was more severe in patients with porphyria cutanea tarda. An overload of lipid and iron, unrelated to the severity of the histological lesions, is common to both porphyrias. The most frequent findings were altered mitochondrial forms and increased numbers of autophagic vacuoles. Lipofuscin bodies were electron dense, large and increased in number, and contained extensive areas of ferritin deposits. An iron overload probably plays an important role in hepatocyte damage.

9389 JAUNDICE IN PREGNANCY. A FOLLOW-UP STUDY OF WOMEN ORIGINALLY REPORTED BY L. THORLING. II. PRESENT HEALTH OF THE WOMEN. *(E.)* Fruhoff, A. K.; Hellstrom, K. (Dept. Med., Karolinska Inst., Stockholm, Sweden). *Acta Med. Scand.* 196(3):181-189, 1974.

In 1955, L. Thorling reported on 71 pregnant women with jaundice, due to cholestasis of pregnancy or infectious hepatitis. Of the original number, 6 women had died and 4 were unwilling to participate in the 1970 follow-up. Of the remaining 61 women (aged 40-60 yr), only 44 participated in the complete study which consisted of a standardized questionnaire, oral cholecystography (where desirable), plus physical and laboratory examinations. Eight women had a moderately abnormal BSP retention unaccounted for by known disease; 3 of these had had symptoms compatible with recurrent cholestasis of pregnancy. In general, all the women considered themselves to be in good health and there were few indications of liver disease. Three of the women who died had severe kidney disease and uremia, and 12 survivors had symptoms of pyelitis and/or nephrolithiasis, pointing to the possible association between jaundice of pregnancy and renal diseases.

9390 HEPATIC PARENCHYMA WEIGHT CHANGES IN THE PRESENCE OF PRIMARY AND SECONDARY TUMORS OF THE LIVER: A MORPHOMETRIC STUDY. *(E.)* Ludwig, J.; Elveback, L. R. (Mayo Clin., Rochester, Minn.). *Beitr. Pathol.* 153(3):280-288, 1974.

Morphometric studies were performed on tumorous livers of 50 patients (24 men and 23 women, aged 26-94 yr). The hepatic parenchyma of all but 6 (13%) of the adult livers weighed more than 1 kg. Of the tumor-bearing livers, 28% had parenchymal weights exceeding the estimated 95th percentile in non-tumor controls. Loss of hepatic parenchyma in tumor-bearing livers is seldom severe enough to cause hepatic failure (only in 2 of the 8 cases of hepatic failure did the liver weigh less then 1 kg.). The right lobe of the liver is definitely favored in the distribution of tumors within this organ.

9391 POSSIBLE ROLE OF THIOL GROUPS IN THE ABNORMAL KINETICS OF ALDOLASE IN HEREDITARY FRUCTOSE INTOLERANCE. *(E.)* Lemmonnier, F.; Gregori, C.; Schapira, F. (Inst. Mol. Pathol., Paris, France). *Biochem. Biophys. Res. Commun.* 61(1):306-312, 1974.

Liver aldolase from 6 children with hereditary fructose intolerance had an abnormal affinity for fructose-1-phosphate. The apparent K_m of the aldolase for fructose-1-phosphate was 15-20 mM compared with 3.0-5.0 mM in normal liver extracts. Extraction and incubation with β-mercaptoethanol (10 mM) lowered the apparent K_m of aldolase in livers of the children with inherited disease to about 3 mM or less. The apparent K_m of aldolase C from human brain was 15 mM and, like the apparent Km of normal liver aldolase, did not change with addition of β-mercaptoethanol. The results suggest that the primary defect of hereditary fructose intolerance involves, directly or indirectly, the thiol groups of aldolase b.

9392 X-RAY MICROANALYSIS OF HEPATIC THORIUM DEPOSITIONS. *(E.)* Terzakis, J. A.; Sommers, S. C.; Snyder, R. W.; Sabbath, M. (Lenox Hill Hosp., New York, N.Y.). *Arch. Pathol.* 98(4):241-242, 1974.

A 49-yr-old woman was admitted with elevated serum alkaline phosphatase and SGOT levels. Previous history revealed a right cerebrovascular accident at age 23 due to aneurysm. A liver biopsy revealed granular deposits in Kupffer cells and in histiocytes within a fibrotic area of a portal space. Transmission electron microscopy, histioautoradiography, and x-ray microanalysis confirmed that these deposits contained thorium or an isotope of thorium.

9393 MORPHOLOGICAL AND BIOCHEMICAL STUDIES ON LIVER BIOPSIES OF PARKINSONIAN PATIENTS TREATED WITH LEVODOPA AND DECARBOXYLASE INHIBITOR. *(E.)* Nevalainen, T.; Riekkinen, P.; Rinne, U. K.; Sonninen, V. (Dept. Neurol., Univ. Turku, Finland). *Acta Neurol. Scand.* 50(1):122-130, 1974.

Needle biopsy specimens were obtained from 10 patients with Parkinson's disease prior to and at 6 months or 1 yr after combined p.o. treatment with L-Dopa (800-1000 mg/day) and a decarboxylase inhibitor, N^1-(DL-seryl)-N^2-(2,3,4,-trihydroxybenzyl)-hydrazine (200-250 mg/day). Biopsies were examined by light and electron microscopy. Enzyme activities (alkaline and acid phosphatase, acid proteinase, glucose-6-phosphatase, leucine aminopeptidase, β-glucuronidase) were studied biochemically to determine possible sublethal inhibitor effect on cell injury. There were no constant histologic or ultrastructural findings, or changes in enzyme activities, which could be related to treatment with L-dopa and decarboxylase inhibitor. Mitochondria, endoplasmic reticulum, and areas of glycogen deposits appeared similar both before and during treatment. Frequency of cytoplasmic lipid droplets and amounts of lipofuscin pigment appeared unaffected by treatment. While acid and alkaline phosphatase values were significantly increased at 6 months, biopsies obtained at 1 yr showed no significant changes in enzyme activities. Combined treatment with L-dopa and decarboxylase inhibitor, at the dosage used, appears to be well tolerated and nontoxic during treatment periods of 6 months to 1 yr.

9394 THE DIAGNOSTIC SIGNIFICANCE OF SERUM ALPHA-FETOPROTEIN. *(E.)* Azzopardi, A. (Dept. Pathol., Roy. Univ., Valletta, Malta). *Tumori* 60(3):231-235, 1974.

Eight patients with suspected extrahepatic neoplasms were tested for serum α-fetoprotein. Seven were positive and 3 of these patients had confirmed hepatocellular carcinoma. A 4th patient had a liver biopsy which showed pleomorphic malignant cells consistent with hepatocellular carcinoma, but a metastatic adenocarcinoma could not be ruled out. The remaining 3 cases were a papilary cystadenocarcinoma of the ovary, a primary adenocarcinoma of the bronchus and a primary bile duct carcinoma. These last 3 cases had wide spread metastases with tumor deposits in the liver. The only case with undetectable serum α-fetoprotein proved to be a hepatocellular carcinoma arising in a cirrhotic liver. It is concluded that serum α-fetoprotein can be detected in a large number of patients with hepatocellular carcinoma, in primary cancers of the gastrointestinal tract and its embryonic outgrowths, as well as in multipotential germinal tumors. The occasional presence of serum α-fetoprotein found in hepatitis, cirrhosis and biliary atresia suggests that the fetoglobulin can also be produced by benign proliferation of liver cells.

9395 HEREDITARY HAEMORRHAGIC TELANGIECTASIA OF THE LIVER DEMONSTRATED ANGIOGRAPHICALLY. *(E.)* Thomas, M. L.; Carty, H. (St. Thomas Hosp. Med. Sch., London, England). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 15(4):433-438, 1974.

A 41-yr-old woman with known hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) of lips and fingertips was admitted with hepatomegaly. On two previous admissions she had undergone cholecystectomy for calculi with vagotomy and pyloroplasty for chronic duodenal ulcer and laparotomy for obstructive jaundice caused by calculi in the common duct. Liver biopsies were obtained both times. The second specimen showed dilatation of the sublobular portal tracts and central veins producing areas of angiomatoid cystic venous dilatation typical of the telangiectatic lesions of Osler's disease. It was decided that the patient should have an angiographic study. Selective catheterization of the celiac axis and hepatic artery proved impossible. Instead, a flood aortic injection of 80 ml Conray 420 was made with the patient prone and a series of films of the hepatic region were taken with an AOT film changer. The examination showed an enormously dilated celiac axis with a diameter comparable to the aorta's. Extreme dilatation and tortuosity of the hepatic artery and its branches was also present, indicating a greatly increased blood supply to the liver. In the hepatographic phase the contrast medium was present in numerous diffuse scattered pools 1-2 cm in size. It is suggested that a differential diagnosis must exclude primary hepatoma, hepatoma arising in a cirrhotic liver, metastases and cavernous hemagioma, since all of these lesions show an increased vascularity.

9396 A LIGHT AND ELECTRON MICROSCOPIC STUDY OF THE LIVER IN CASE OF ERYTHROHEPATIC PROTOPORPHYRIA AND IN GRISEOFULVIN-INDUCED PORPHYRIA IN MICE. *(E.)* Matilla, A.; Molland, E. A. (London Hosp., England). *J. Clin. Pathol.* 27(9):698-709, 1974.

A 30-yr-old woman, who had been taking a birth control pill for 18 months, had a history of photosensitivity for 9 months. Laboratory investigations gave the following data: hemoglobin, 12.4 g/100 ml; erythrocyte sedimentation rate, 41 mm in the 1st hr; alkaline phosphatase, 16.0 King-Armstrong U/100 ml; SGOT 50 IU/100 ml; bilirubin, 0.8 mg/100 ml; BSP, 15% retention at 45 min. Red cell porphyrins and fecal porphyrins were well above normal. Biopsy of skin from the hand showed *p*-aminosalicylic-positive hyaline material around the papillary vessels. Twenty male mice weighing about 25 g at the beginning of the experiment were given griseofulvin in diet and sacrificed at intervals beginning at 24 hr and lasting for 5 wk. Animal livers and the patient's biopsy specimen were examined by light- and electron-microscopy. In both cases crystals were present in hepatocytes and in the bile secretory pathways. Spectroscopic studies confirmed that the crystals in the human and animal livers contain protoporphyrin. The morphological similarities between the animal and human livers suggest a primary hepatic lesion in each case, but do not provide information about the mechanisms leading to protoporphyrin accumulation. It is suggested that there may be cases within the group of erythrohepatic protoporphyrias where the principal lesion is in the liver. In the case reported here, the pill may have elevated the liver aminolevulinic acid synthetase level sufficiently to cause accumulation of protoporphyrin in a previously abnormal but compensated system.

9397 SERUM UROCANASE IN TOXICITY TESTING. *(E.)* Trip, J. A. J.; van Dam, J.; Eibergen, R.; Que, G. S. (no affil.). *Food Cosmet. Toxicol.* 12(4): 588-589, 1974.

The correlation between serum levels of urocanase (specific liver enzyme) and histologic findings in needle-biopsy specimens from 186 patients with liver disease or hepatic dysfunction was examined. Good agreement between both was present in 75% of the patients, but similar correlations were also established for SGOT and SGPT (not liver-specific enzymes). Since urocanase determination is fairly time-consuming and not clearly superior, it is not an appropriate choice for routine laboratory study of liver damage.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

9434 HAEMOPERFUSION FOR JAUNDICE. *(E.)* Anonymous. *Br. Med. J.* 5929(3):486-487, 1974.

Bilirubin was removed *via* column hemoperfusion using a particle completely different from negatively charged resins. Albumin was bound to agarose beads by a technique for coupling proteins to insoluble polysaccharides and bilirubin was effectively removed from blood passed *in vitro* through a column of these beads without damage to either red cells or platelets. This new column is safe and removed only those substances which bind to albumin. The successful removal of unconjugated bilirubin from Gunn rats is of interest for children with an enzyme defect similar to that of the Gunn rat which lacks the hepatic microsomal enzyme to conjugate bilirubin with glucuronic acid before it is excreted as conjugated bilirubin into the bile. Children most severely affected develop irreversible brain damage or kernicterus in infancy from the very high blood levels of unconjugated bilirubin. Weekly hemoperfusion may sufficiently lower the blood bilirubin levels in these children. The more common clinical problem, the treatment of deep conjugated hyperbilirubinemia and persistent itching due, for example, to prolonged cholestasis from carcinoma of the biliary tree or primary biliary cirrhosis, may also be alleviated by such hemoperfusion. It is noted however that bile salts, which probably cause the itching, bind less firmly to albumin and would therefore not be so well removed by the agarose-bound albumin columns. The treatment of fulminant liver failure due to viral hepatitis or overdosage with paracetamol has employed column hemoperfusion with particles of charcoal coated with polyhema. It is not known which of the many substances that accumulate in blood during liver failure cause hepatic encephalopathy. It is suggested that 2 columns may be needed to fully reverse liver failure, one for removing water-soluble toxins and the other, such as a column of agarose-bound albumin, for protein bound compounds.

9435 THE INFLUENCE OF PHENOBARBITONE ON BILIRUBIN CLEARANCE. *(E.)* Heringova, A.; Jirsova, V. (Inst. Care Mother Child, Prague, Czechoslovakia). *Biol. Neonate* 23(5-6):325-329, 1973.

The effect of phenobarbital on bilirubin clearance was evaluated in 40 newborn infants with regard to the maturation process of the hepatic chromosecretoric function. Mothers of 10 infants born at term were given phenobarbital (100 mg/day p.o., 7-14 days before delivery). Ten premature infants were given phenobarbital (8 mg/kg/day in 3 divided doses p.o., from 6 hr to 4 days of life). A group of 10 full term and 10 premature infants served as controls. Initial serum bilirubin levels at 6 hr after birth were 2.6 mg/100 ml. On day 5 in control term infants and in control premature infants, the serum bilirubin levels were 6.0 ± 1.3 and 9.9 ± 0.6 mg/100 ml, resp. On day 1 of life, bilirubin clearance from the plasma was very slow for both term and premature infants in the control group; 37% and 45%, resp. of the injected pigment were still retained at 3 hr. In term infants born of mothers treated with phenobarbital, injected pigment was excreted within 2 hr. On day 5, control term infants excreted all injected bilirubin within 1 hr. In control premature infants, 40% of the administered bilirubin remained in circulation 3 hr after injection. Premature infants given phenobarbital since day 1 excreted all administered bilirubin within 80 min. No serious complications were encountered in infants receiving the drug or in those born to treated mothers. Activity reduction was the only sign noted in the treated premature infants. This study shows that phenobarbital given to mothers during pregnancy or to infants since day 1 enhances bilirubin clearance in newborns. It is suggested that when jaundice appears in term infants, the chromoexcretory capacity of their livers may be almost "normal" so that the beneficial effect of phenobarbital cannot be observed. Prophylactic administration of phenobarbital seems to be indicated in premature infants who may suffer from irreversible brain damage as a result of hyperbilirubinemia.

9436 CLINICAL AND GENETIC STUDIES ON DUBIN-JOHNSON SYNDROME IN A CLUSTER AREA IN JAPAN. *(E.)* Kondo, T.; Kuchiba, K.; Ohtsuka, Y.; Yanagisawa, W.; Shiomura, T.; Taminato, T. (Uwajima City Hosp., Ehime, Japan). *Jap. J. Hum. Genet.* 18(4):378-392, 1974.

Identification was made of 40 patients with definite and 8 with probable Dubin-Johnson syndrome in an isolated area in Japan. They belonged to 25 sibships in 22 families. The sex of the patient was not a significant factor. The majority of the families lived in the Tsushima-Minamiuwa district. Of the 3 families living outside this district, each had ancestors who had immigrated from Tsushima. All 22 families belonged to the peasant-fisher class. The estimated segregation ratio in sibs with normal parents was 0.218 ± .00219. Parental consanguinity among sibships with Dubin-Johnson syndrome was observed in 52%. The rate of consanguineous marriages in 415 married couples randomly selected in the cluster area was 12.3%. The mean BSP transport maximum (Tm) in 7 patients with the syndrome was virtually zero, but that in 11 normal controls and in 13 carriers was 7.2 and 5.2 mg/min, resp. The findings of a late increase in serum BSP and a decreased Tm with normal relative storage capacity of BSP are pathognomonic features of Dubin-Johnson syndrome. A black liver is suggestive, but the histologic finding of cytoplasmic granules alone is not pathognomonic. The data are consistent with an autosomal recessive mode of inheritance in Dubin-Johnson syndrome. Patients with the other types of constitutional nonhemolytic hyperbilirubinemia, including Rotor type, were not identified in these 22 families.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

9446 BLOOD LEVELS OF RIFAMPICIN IN LIVER DISEASES. *(E.)* Pozzi, E.; Menghini, P. (Fac. Med., Univ. Pavia, Italy). *Int. J. Clin. Pharmacol.* 10(1):44-49, 1974.

A group of 15 male tuberculous patients (34-56 yr of age), divided into subgroups of 10 patients with a BSP retention value greater than 7% at 45 min and 5 patients with normal liver functions, were administered rifampicin (600 mg in the morning and 300 mg 8 hr later), isoniazid (600 mg/day at 12 hr intervals), and ethambutol (1600 mg/day at 12 hr intervals). BSP and other liver function tests were performed during the trials along with rifampicin blood level measurements. Jaundice appeared in 8 patients in the 1st group within 5-7 days after drug administration began. None of the patients in group 2 showed any sign of jaundice. The jaundice regressed within 4-10 days after withdrawal of rifampicin. Rifampicin alone was administered at the same dosage on Tuesday and Friday for 2 weeks to 4 of the 8 patients previously showing jaundice, and no signs of jaundice appeared in this trial. Triple-drug therapy (twice a week) was thus resumed in these 4 patients. A good correlation was found between a 16% or more retention value for BSP (at 45 min) and the appearance of jaundice. Serum values of rifampicin were much higher in subjects with altered BSP excretion, including those patients resuming rifampicin in an intermittent regimen after discontinuation because of jaundice. Rifampicin appeared to be directly responsible for the jaundice and should be administered in lower doses to subjects with impaired liver function.

9447 DIPHENYLHYDANTOIN-INDUCED HEPATIC NECROSIS. *(E.)* Dhar, G. J.; Ahamed, P. N.; Pierach, C. A.; Howard, R. B. (Northwestern Hosp., Minneapolis, Minn.). *Postgrad. Med.* 56(1):128-134, 1974.

A case of diphenylhydantoin-induced hepatic necrosis in a previously healthy 20-yr-old woman is described. After taking the drug for 15 days as prescribed (100 mg p.o., 3 times a day), the patient presented with symptom complex of fever, rash, and generalized lymphadenopathy. Diphenylhydantoin was discontinued and phenobarbital was prescribed. Phenobarbital was discontinued after the patient revealed that she had been exposed to a neighbor with rubella. Marked improvement occurred during the next 5 days, and diphenylhydantoin was thus restarted. A recurrence of the symptoms occurred within 5 days; the patient now had extensive desquamating morbilliform rash covering the entire body, generalized lymph node enlargement, tachycardia, hepatomegaly of 4 fingerbreadths, jaundice, and a positive tourniquet test for capillary fragility. Total serum bilirubin was 3.8 mg/100 ml, alkaline phosphatase was 210, SGOT 118, and LDH 481 IU/ml. Treatment with prednisone was unsuccessful and the patient died in a state of profound toxemia with hemorrhagic manifestations rather than in hepatic failure even though the striking pathologic finding at post mortem was diffuse hepatic necrosis. Immediate withdrawal of diphenylhydantoin at the first sign of a possible adverse reaction appears mandatory in treating the condition which closely resembles rubella. Corticosteroids may or may not suppress the hypersensitivity phenomenon.

9448 STUDY OF THE EFFECT OF RIFAMPICIN ON THE LIVER. *(E.)* Laudano, O. M. (Centenario Hosp., Rosario, Argentina). *Tijdschr. Gastroenterol.* 16(41):283-294, 1973.

Rifampicin (600 mg/12 hr for 15 days) was administered to 15 subjects with normal liver function and 15 subjects with liver disease (average age for both groups 43 yr) to investigate the effect of the antibiotic on the liver. The subjects with liver disease consisted of 4 cases of fatty liver, 2 with liver metastases, 1 with active chronic hepatitis, and 8 with cirrhosis. Liver function tests (direct and indirect reacting serum bilirubin, alkaline phosphatase, SGOT, SGPT, and BSP retention at 45 min) were performed before treatment, on the 7th day, and at the end of treatment. All normal subjects showed normal liver function values and no other abnormalities; the same was true for 4 patients with fatty liver. The 2 patients with liver metastases became jaundiced on the 12th and 15th day of treatment, resp., with remission of the jaundice in 3-4 days after discontinuation of the drug. The jaundice was associated with an increase of the 2 bilirubin values only, and no evidence of cytolysis or cholestasis was apparent. Jaundice appeared on the 7th day and showed remission after 3 days in the patient with active chronic hepatitis who was also receiving prednisone (40 mg/day). Five of 8 patients with cirrhosis became icteric on the 3rd, 4th, 5th, 9th, and 10th day of treatment, resp. The remaining 3 cirrhotic patients showed serum bilirubin values at the upper limit of normal. In all cases jaundice remitted on the 3rd or 5th day, without increase in transaminases or alkaline phosphatase and without changes in the BSP clearance values. The elevated values of free and conjugated bilirubin associated with jaundice reached a high of 39.1 mg% (total serum bilirubin).

9449 ANGIOGRAPHY IN RADIATION "HEPATITIS". *(E.)*

Nebesar, R. A.; Tefft, M.; Vawter, G. F.; Filler, R. M. (Children's Hosp. Med. Ctr., Boston, Mass.). *Br. J. Radiol.* 47(561):588-593, 1974.

Selective celiac, hepatic, splenic, and superior mesenteric angiography was used to evaluate radiation hepatitis in 5 children (16 months to 6 yr of age). Each had been treated for Wilms' tumor and had received routine post-operative abdominal irradiation to the tumor bed. The angiograms were correlated with liver scans taken during routine follow-up and with biopsy results. The angiographic and pathologic findings correlated well. During the acute phase, when hepatic venule obstruction and lobular congestion were present, the angiogram showed enlargement of the affected region with stretching of the hepatic arteries and retrograde (hepatofugal) flow in intrahepatic portal vein branches. In the chronic recovery phase, there was a compensatory hypertrophy of non-irradiated areas with stretching of hepatic arteries and atrophy and fibrosis of the irradiated region which showed crowding and corkscrewing of the hepatic arteries with normal hepatopetal portal venous flow. By combining scanning and angiography, the correct diagnosis can often be suggested, thus avoiding re-exploration, especially during the chronic phase of radiation injury.

9450 HEPATOTOXICITY OF PAPAVERINE. HISTOLOGIC LESIONS. *(E.)*

Kiaer, H. W.; Olsen, S.; Ronnov-Jessen, V. (Commun. Hosp., Frederiksborg, Denmark). *Arch. Pathol.* 98(5):292-296, 1974.

Biochemical and liver biopsy findings are presented for 8 patients (6 women and 2 men, ages 58-90 yr) exhibiting liver injury during treatment with papaverine (80 mg p.o. 4 times/day for about 1 month in most cases). Alkaline phosphatase, SGPT, and SGOT liver function indices were elevated in all cases. Subjective complaints (oppression or pain in the epigastrium) and fever were experienced in 4 of the 8 patients. The most important biopsy findings for the group as a whole were: significant eosinophilia in the portal spaces, focal eosinophilia in the hepatic parenchyma, and diffuse proliferation of the Kupffer cells. The degree of eosinophilia varied among different patients on the same dosage of papaverine and was thus independent of dosage. Cholestasis was not present in any of the patients. One patient exhibited a normal hepatic structure. The lesions were reversible in 7 of the patients; 1 patient, a 90-yr-old woman, died of a fresh myocardial infarction 3 days after liver biopsy. Abnormal liver function regressed in 2 of the patients despite continued treatment with papaverine. The hepatotoxic action of papaverine appears to include an allergic factor.

9451 LONG-TERM FOLLOW-UP OF NEONATAL HEPATITIS: SAFETY AND VALUE OF SURGICAL EXPLORATION.

(E.) Lawson, E. E.; Boggs, J. D. (Children's Mem. Hosp., Chicago, Ill.). *Pediatrics* 53(5):650-655, 1974.

A retrospective analysis of the long-term course of either familial (5 cases) or sporadic (18 cases) neonatal hepatitis in 23 children was performed to evaluate the safety and value of surgical exploration for this condition. All 5 patients with familial disease and 9 with sporadic disease underwent diagnostic laparotomy and liver biopsy; surgery was not performed on the remaining 9 sporadic cases. More patients subjected to surgery died than patients in the nonsurgical group (4 deaths *versus* 1 death, resp.). Familial cases accounted for 2 of the 4 deaths among the group undergoing surgery. No statistically significant difference in outcome, however, appeared at long-term follow-up between the operative and nonoperative sporadic groups when familial cases were excluded from the total surgical group. Early laparotomy of infants with neonatal hepatitis who lack a positive family history is therefore considered safe and useful in establishing the diagnosis and in salvaging a small number of infants with surgically correctable biliary atresia.

9452 THE COMPLEXITIES OF PYRROLIZIDINE ALKALOID TOXICITY. *(E.)*

Cooper, P. (no affil.). *Food Cosmet. Toxicol.* 12(4):559-563, 1974.

Senecio species have been implicated in liver disease and primary liver tumors in developing countries where natural products are used for medicinal and cooking purposes. The alkaloids incriminated in these toxic effects include retrorsine, monocrotaline, fulvine, lasiocarpine, heliotrine, and senkirkine. All are esters of 1-hydroxymethyl-1,2-dehydropyrrolizidine and are probably metabolized by liver microsomal-enzyme systems to hepatoxic pyrroles. Prolonged administration of retrorsine (20 mg/kg p.o. through stomach tube) to vervet monkeys produced hepatic fibrosis and vaso-occlusive liver lesions. Pulmonary and myocardial changes were the principal findings in stumptail monkeys given monocrotaline (30 mg/kg s.c.) at age 1 month. Experiments in rats given monocrotaline (5-10 mg/kg i.v.) did not support the suggestion that 5-hydroxytryptamine in an effective intermediate in the pulmonary activity of the alkaloid. The overall toxicity of monocrotaline to rats depends on the level of hepatic microsomal activity. Prior treatment with phenobarbital resulted in earlier and more severe lung lesions and earlier death from 60 mg/kg monocrotaline. Chloramphenicol prevented death after this dose and ameliorated the acute lesions but did not prevent chronic liver lesions. Retrorsine and monocrotaline are more toxic to male rats than to females. Also, sensitivity of rats to lasiocarpine, heliotrine, and retrorsine increases with age, reflecting the capacity of the liver to produce and retain pyrroles. In contrast to the above-mentioned findings in young stumptail monkeys, monkeys given monocrotaline from 15 months on showed prominent ascites and increased portal venous pressure. Postmortem findings included granular livers with venous occlusion. These differences in organ sensitivity were attributed to differences in microsomal-enzyme levels and resulting differences in liver metabolite concentrations. Experiments in sheep provided no evidence that the effects of reduced methane production on the metabolism rate would afford protection for the target organs of pyrrolizidine metabolites.

9453 HEPATIC INJURY ASSOCIATED WITH NITROFURANTOIN THERAPY. *(E.)* Goldstein, L. I.; Ishak, K. G.; Burns, W. (DeWitt Army Hosp., Fort Belvoir, Va.). *Am. J. Dig. Dis.* 19(11):987-998, 1974.

Clinical and biochemical findings are reported for 2 patients (a 50-yr-old woman and a 44-yr-old man) who developed hepatic injury while taking nitrofurantoin for urinary tract infections. The female patient had been taking 400 mg/day p.o. nitrofurantoin for 5 weeks, while the male patient had taken a total dose of 60 g p.o. The major biochemical abnormality was elevation of serum transaminase values. SGOT and SGPT for the female were 250 and 100 U, resp. and for the male patient 120 and 65 U, resp. Readministration of nitrofurantoin (100 mg 4 times/day) to the male patient resulted in hypertransaminasemia (SGOT 250 U and SGPT 110 U). The light-microscopic and ultrastructural findings from hepatic biopsy specimens of both patients were those of a predominantly hepatocellular type of injury. The female patient exhibited scattered foci of intralobular necrosis and inflammation as well as sinusoidal acidophilic bodies. Electron microscopic examination revealed additional hepatocellular injury in the form of light cells and a relatively minimal degree of cholestasis. The other patient exhibited similar changes which were quantitatively more severe than those from the female's biopsy specimen. Comparison of these 2 cases with 6 other reported cases indicates that all patients but 1 were female and ranged between the ages of 31-65 yr. All patients had taken the drug p.o. The onset was usually sudden. There appears to be no relationship between dosage and the occurrence of the nitrofurantoin-associated illness.

9454 TALC GRANULOMATA IN LIVER DISEASE IN NARCOTIC ADDICTS. *(E.)* Min, K. W.; Gyorkey, F.; Cain, G. D. (VA Hosp., Houston, Tex.). *Arch. Pathol.* 98(5):331-335, 1974.

Liver biopsy results are presented for 16 male known drug users (ages 19-29 yr) with clinical hepatitis. The sera from 9 patients at the time of biopsy were positive for hepatitis-associated antigen (HAA). The microscopic changes were those of acute viral hepatitis in 7 patients; 8 patients had chronic aggressive hepatitis, and 1 had chronic persistent hepatitis. Additionally, there were prominent portal infiltrations which consisted of small lymphocytes, a few plasma cells, and rare granulocytes. There were also histiocytes with vacuolated foamy cytoplasm forming pseudogranulomata. These infiltrates were present throughout the hepatic lobules in 4 patients. The histiocytes examined under polarized light disclosed birefringent crystalline inclusions; these were needle-shaped, 5-12 μ long and morphologically consistent with talc granules. There were also occasional starch-containing histiocytes. The findings suggest that the filler substances in drugs (talc, for example) used i.v. may have an etiological role either singly or in combination with other factors (such as viruses) in chronic liver disease of drug users.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

9465 DANE COMPLEXES IN HEPATITIS B ANTIGEN. *(E.)* Moodie, J.; Stannard, L. M.; Kipps, A. (Med. Sch. Observatory, Cape Town, South Africa). *J. Gen. Virol.* 24(2):375-379, 1974.

Electron microscope observations of Dane complexes in hepatitis B antigen (HBAg)-positive sera are presented as evidence of an antigen-antibody system involving only the Dane coat material. Sera with large quantities of HBAg and numerous Dane particles, but with no detectable antibodies to surface antigens were subjected to agitation in chloroform for 5 sec or treatment with 0.01% mucasol overnight at room temperature and showed the formation of numerous and large complexes of Dane particles including 'tadpole' forms. The action on the lipoprotein of either chloroform or mucasol altered the surface structure of the Dane coats and the small spheres and tubules. Since the latter remained unaggregated the complexing of Dane particles appeared to be specific and significant. Treatment of a HBAg-immunoglobulin concentrate overnight with mucasol or with 0.25% deoxycholate resulted in aggregation into large complexes of damaged Dane particles, free cores, and free coats, with core antibody molecules attached to the exposed cores and linking some cores together. Incubation of the antigen-immunoglobulin concentrate for 1 hr at 37 C with 0.6 U/ml of protease, followed by deoxycholate treatment at 4 C overnight resulted in electron micrographs which differed from those obtained by exposure of the antigen to the bile salt alone. Small spheres and tubules were present in damaged form but not aggregated. Although Dane particles and particle coats were absent, there were large complexes of Dane particle cores linked together by anti-hepatitis B immunoglobulin similar to that previously shown for the immunoglobulin G of anti-HB_c on the core surface. These observations suggest the presence of a hidden Dane-coat antigen which is not present in the small spheres (20 nm) or in the tubules and which is destroyed by protease treatment.

9466 A SEROLOGICAL TOOL FOR THE DIAGNOSTICS OF VIRUS B HEPATITIS. *(E.)* Kjeldsberg, E.; Traavik, T.; Siebke, J. C. (Natl. Inst. Public Health, Oslo, Norway). *Acta Pathol. Microbiol. Scand.* [B] 82(3):396-402, 1974.

A new antigenic determinant (associated with the 27 nm core of the Dane particle) in virus B hepatitis was detected with the closed hexagon immunodiffusion test (a modified gel precipitation test). Hepatitis B antigen (HBAg)-positive serum of a chronic hepatitis patient treated with Tween 80 and with posthepatic sera negative for HBAb, had aggregates of 27 nm particles, some randomly distributed 20 nm particles, and some short disintegrating tubules. Tween 80 alone or with HBAg-negative serum produced no precipitation lines. Post hepatitis sera negative for HBAb, commercial human HB-antiserum and HBAb serum from a long-term carrier all produced precipitation lines when exposed to the detergent-treated serum (HBAg-positive and containing Dane particles) of a patient with chronic hepatitis. Precipitation lines were stronger with Tween 80 than without. It is assumed that the antigenic components of this new system are different from HBAg determinants as demonstrated in the modified gel precipitation test.

9467 PURIFICATION OF NAKED INTRANUCLEAR PARTICLES FROM HUMAN LIVER INFECTED BY HEPATITIS B VIRUS. *(E.)* Hirschman, S. Z.; Gerber, M.; Garfinkel, E. (Mt. Sinai Sch. Med., New York, N.Y.). *Proc. Natl. Acad. Sci. USA* 71(9):3345-3349, 1974.

Naked intranuclear particles from a human liver infected with hepatitis B virus were purified by a procedure that entailed isolation of the liver nuclei, the subsequent release of the naked intranuclear particles from the nuclei by sonication, and the purification of the particles on CsCl density gradients. The particles had a diameter of 27-28 nm, were hexagonal and showed the presence of capsomeres and spikes with lengths of 7-10 nm projecting from the surface. The particles formed cubic arrays with center-to-center distances of 40-42 nm. The overall particle symmetry was icosahedral. The UV absorption spectrum of the particles showed a peak at 264 nm with a shoulder at 280 nm. Endogenous DNA polymerase activity was present when activated DNA or d(A-T)n was used as exogenous template.

9468 C.E.A. IN 1974. *(E.)* Anonymous. *Br. Med. J.* 5929(3):484-485, 1974.

Among 192 patients who had undergone potentially curative surgery for colorectal cancer, serum carcinoembryonic antigen (CEA) titers rose progressivly in 6 asymptomatic patients in whom clinical examination revealed metastases. In 1 case, the CEA titer remained raised for 29 months before diagnosis was confirmed. In another series of 220 patients with apparently successful resections, progressive rises in CEA due to metastases occurred in 26 patients 8-18 months before confirmation of the diagnosis. Raised titers in 10 other patients were noted synchronously with clinical detection of tumor; a further 17 patients have a raised CEA but are asymtomatic and without clinical evidence of tumor. The increase in CEA was more marked for hepatic metastases than for nonhepatic metastases.

Chronic Hepatitis

9499 ASYMPTOMATIC HEPATITIS B ANTIGEN CARRIERS: A CLINICOPATHOLOGICAL STUDY. *(E.)*

Fainaru, M.; Levij, I. S. (Hadassah Univ. Hosp., Jerusalem, Israel). *Acta Hepatogastroenterol.* 21(3):186-191, 1974.

A follow-up study performed on 6 asymptomatic chronic hepatitis B antigen carriers with no previous history of hepatitis revealed abnormal liver function tests (increased SGOT, SGPT, serum iron, or vitamin B_{12}) in 4 and abnormal histological findings of minimal chronic persistent hepatitis in 3. Biopsies showed moderate or slight mononuclear cell infiltration of portal space and, in 2 cases, a group of swollen Kupffer cells intermingled with lymphocytes. An additional finding in 1 biopsy was slight pleomorphism of liver cells near central vein branches, with a few binucleated liver cells. Only 1 patient with abnormal liver histology had abnormal liver function tests. In the 2-yr follow-up no deterioration of liver function was found in any of the 6 cases. The results are in agreement with other reports claiming that the carrier state is associated with liver damage which may remain unchanged for 2 or more yr.

9500 INFUSION OF HEPATITIS B ANTIBODY IN ANTIGEN POSITIVE ACTIVE CHRONIC HEPATITIS. *(E.)*

Reed, W. D.; Eddleston, A. L. W. F.; Williams, R.; Zuckerman, A. J.; Peters, D. K.; Maycock, W. D'A. (King's Coll. Hosp., London, England). *Aust. NZ J. Med.* 4(3):301, 1974.

Infusion of high-titer antibody to hepatitis B antigen (HBAg) in 6 patients with antigen-positive active chronic hepatitis induced a fall in HBAg (complement fixation) titers only in patients with initially low titers. The effect was temporary. Apart from transient microscopic hematuria in 1 patient and slightly increased proteinuria in another, there was no evidence of systemic immune-complex disease. Ag/Ab complexes were demonstrated prior to infusion in 3 patients, as well as immediately after infusion in 4. Of 5 patients with serum complement (C3) conversion products detectable after infusion, 3 showed the products before treatment.

9501 HISTOENZYMOLOGIC ANALYSIS OF THE SPECIFIC LIVER CATHEPSINS WITH REFERENCE TO THE PATHOLOGY OF EPITHELIOCONNECTIVE RELATIONSHIP. *(E.)*

Gabrielescu, E.; Bordeianu, A. (Dr. V. Babes Inst. Pathol. Med. Genetics, Bucharest, Rumania). *Rom. Med. Rev.* 18(1):6-16, 1974.

Activity of proteolytic enzymes was studied in liver biopsies from patients with chronic liver disease and in livers of rats with chronic hepatitis induced by tannic acid. The histochemical reaction of cathepsin D coincided with the dystrophic area in liver with proteolipid dystrophy. In cases of autolytic or cytolytic reactions, cathepsin D activity was intense in the contact zone between proliferating mesenchyma and epithelium, corresponding to alterations in lysosomal permeability. In chronic evolutive diseases with an active mesenchyma, cathepsin D was predominant in Kuppfer cells and was increased in inflammatory infiltrate within the parenchyma. Tryptase was present in intralobular inflammatory infiltrate and tended toward intracystoplasmatic diffusion in zones of mesenchymal aggression. Chymase was present only in mast cells, while cathepsin C was active only in hepatic epithelia. Leucyl-β-naphthylamidase activity was intense in biliary canalicular walls, proliferating bile neoducts, and liver cells undergoing biliary dedifferentiation. Histoenzymologic localization of cellular protease activity makes it possible to locate the site of maximum aggression and to differentiate predominantly hepatocytic or predominantly mesenchymal forms of chronic hepatic disease.

9502 CHRONIC HEPATITIS AND INTERSTITIAL CELL INFLAMMATION. *(It.)*

Gallo, G. (Ital. Ctr. Gastroenterol., Rome, Italy). *Rassegna Clin. Sci.* 49(1):24-26, 1973.

Granulomatosis of the liver, resulting from infiltrations of lymphocytes or lymphocytes and monocytes, is considered to be a manifestation of various types of immune phenomena. These lesions can almost always be traced to infectious diseases, particularly chronic diseases. The most common is tuberculosis, followed by rheumatic heart disease and rheumatoid arthritis. Of 120 patients with cirrhosis, seen in a 3-yr period, tuberculosis or rheumatic heart disease were diagnosed in more than 60%, while less than 20% had viral infections. Lymphocytes may develop into plasma cells which have antibody function. Lymphocyte infiltration may regress either spontaneously or in response to antibiotic therapy. The monocytes in lymphocyte and monocyte infiltrates, can develop into fibroblasts which have the ability to produce collagen. On the basis of these infiltrations, it is proposed that chronic hepatitis be classified into 2 types: (1) chronic interstitial or lymphocytic with a benign course and (2) chronic granulomatous or lymphomonocytic with fibrosclerotic course.

9503 CHANGES IN SERUM GLYCOPROTEINS IN CHRONIC HEPATITIS. *(Sp.)*

Ortiz Leyba, C.; Sanchez Guijo, P.; Pachon Diaz, J.; Medina Redonda, F.; Rodriguez Pinero, J.; Nunez Castain, C.; Villar Ortiz, J. (Fac. Med., Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 44(1):45-52, 1974.

After separation by electrophoresis, serum glycoprotein fractions were determined on 8 fasting patients with chronic hepatitis (5 with the aggressive form and 3 with persistent ones) and 24 controls. All glycoprotein fractions studied were increased in patients with chronic hepatitis. This increase was more pronounced for fucose and osamines than for neutral sugars and sialic acid. No changes were observed in total protein levels. When patients with chronic aggressive hepatitis were considered separately, the increase in serum neutral sugars and sialic acid were not significant, but this is attributed to the small number of cases since mean values were the same as for the entire group of hepatitis patients. Among patients with chronic persistent hepatitis, only sialic acid levels were significantly increased. Determinations of serum glycoproteins in the perchloric acid-soluble fraction revealed that all fractions were decreased, but decreases were significant only for sialic acid and perchloric acid-soluble proteins (mucoproteins). The decrease in the mucoprotein fraction was less pronounced among patients with chronic persistent hepatitis. Changes in serum glycoprotein levels observed in chronic hepatitis are probably due to a combination of dysproteinemia and the impairment of carbohydrate synthesis in the liver.

9504 HEPATIC TOLERANCE OF AZATHIOPRINE IN IMMUNOSUPPRESSIVE THERAPY FOR CHRONIC ACTIVE LIVER DISEASE. *(Cz.)*

Nicolaescu, T.; Bittman, E.; Stoiculescu, P.; Bordeianu, A.; Cinotescu, L. (D. Danielopolu Inst. Normal Pathol. Physiol., Bucharest, Rumania). *Cesk. Gastroenterol. Vyz.* 28(1):24-30, 1974.

Administration of azathioprine (1-1.5 mg/kg/day) or azathioprine + prednisone to 40 patients with chronic liver disease, with and without cirrhosis, for 6-28 months and administration of azathioprine (2 mg/kg/day p.o. through a stomach tube) to 77 adult rats for 30 days after 1/3 hepatectomy caused no appreciable liver damage, either in the patients or rats. Double-blind tests, performed on the patients with liver disease, were evaluated by liver biopsies, taken every 3-6 months, and liver function tests, performed before, several times during, and after discontinuation of therapy. Hepatocyte dystrophy and piecemeal necrosis were less common among treated patients than among those given placebos. Hepatocyte synthesis, as measured by decreases in serum albumin and β-lipoprotein levels, was appreciably better in azathioprine-treated patients than in controls. Incorporation of ^{32}P into nucleic acids was reduced by 1/3 in treated patients, but no evidence of nucleic acid denaturation was found. Treatment increased hepatocyte protease and lipids, but no differences in hepatocyte proteins and nucleoproteins or in the rate of liver regeneration were found between treated patients and controls. Azathioprine had no effect on blood bilirubin levels, but there was a higher percentage of treated patients with improved BSP clearance than of treated patients with decreased BSP clearance. Treatment had no significant effect on SGOT or SGPT levels, either in patients or experimental animals. In azathioprine-treated rats, however, serum alkaline phosphatase levels were increased, as was acid phosphatase activity in the liver.

9505 IMMUNE REACTIONS TO HEPATITIS B ANTIGEN IN ACUTE AND CHRONIC HEPATITIS. *(E.)*

Warnatz, H. (Univ. Hosp. Erlangen-Nurnberg, Germany). *Acta Hepatogastroenterol.* 21(4):237-244, 1974.

Lymphocyte cultures from healthy controls and patients with liver disease were incubated with phytohemagglutinin. The response to phytohemagglutinin was impaired in lymphocytes of patients with virus A hepatitis but was normal in patients with virus B hepatitis. A stimulation index over 2 was observed in 2 of 15 patients with serum A hepatitis, 7 of 11 patients with virus B hepatitis, 1 of 3 HBAg-positive postvirus B hepatitis patients (6 months after acute disease), and 6 of 7 patients with HBAg-negative postvirus B hepatitis. Follow-up studies were done on 3 patients whose clinical symptoms of virus B hepatitis appeared 2-3 months after blood transfusions. Lymphocyte stimulation by HBAg correlated with the presence of HBAg detected in serum and the clinical course of the disease. Leukocyte migration was inhibited significantly only in virus B hepatitis. Lymphocytes from 12 controls and 6 patients with postvirus B hepatitis were not stimulated by allogenic antigenic preparations with the exception of soluble liver cell antigen. Liver cell antigens, the soluble fraction in particular, had a stimulatory effect on lymphocytes from several patients with active chronic hepatitis. Mitochondrial preparations stimulated DNA synthesis in 3 patients with circulating mitochondrial antibodies but did not induce increased DNA synthesis in active chronic hepatitis. The data are insufficient to support the hypothesis that chronic hepatitis is due to an inadequate immune reaction of the host to virus B infection.

Alcoholic Liver Disease

9524 REDUCTION IN CIRCULATING T LYMPHOCYTES IN ALCOHOLIC LIVER DISEASE. *(E.)* Bernstein, I. M.; Webster, K. H.; Williams, Jr., R. C.; Strickland, R. G. (Univ. New Mexico Sch. Med., Albuquerque). *Lancet* 2(7879):488-490, 1974.

Peripheral-blood T and B lymphocytes were measured in 49 patients (45 men and 4 women, aged 23-68 yr) with alcoholic liver disease and in 14 chronic alcoholics (26-62 yr old) without clinical evidence of liver disease. Fourteen patients without clinical evidence of liver disease and 7 with only fatty liver had normal proportions and numbers of circulating T cells. A significant reduction of T cells was observed in 42 patients with alcoholic hepatitis and/or cirrhosis, with the reductions being greatest in alcoholic hepatitis. B-cell proportions and numbers were not altered in alcoholic liver disease, though a significant and unexplained increase in B cells was noted in alcoholics without overt liver disease. The mean proportion of rosette-forming T cells in the group with alcoholic hepatitis was 37 ± 19% as compared to a control value of 65 ± 11%. The pronounced decrease in peripheral-blood T cells suggests that there is a basic impairment in cell-mediated immunity in alcoholic liver disease.

Cirrhosis

9536 TRANSHEPATIC CATHETERIZATION AND OBLITERATION OF THE CORONARY VEIN IN PATIENTS WITH PORTAL HYPERTENSION AND ESOPHAGEAL VARICES. *(E.)* Lunderquist, A.; Vang, J. (Univ. Hosp., Lund, Sweden). *N. Eng. J. Med.* 291(13):646-649, 1974.

A transhepatic portographic method for the management of patients with portal hypertension and bleeding esophageal varices is described. The method consists of percutaneous transhepatic portal venipuncture and manipulation of a catheter *via* the portal vein into the coronary vein. The risk of bleeding from esophageal varices is reduced by injection of 30 ml of 50% glucose solution, followed by a few drops of thrombin. The purpose of this injection is to produce a thrombus in the coronary vein that can migrate upward and obliterate the esophageal varices. Portography is used throughout to facilitate the procedure and assess the results. Obliteration of the coronary vein by this method has been successful in 4 patients treated thus far. Case reports for 2 of them (64-yr-old woman and 68-yr-old man, both with varice bleeding) are described. Transhepatic portography of the female patient, previously diagnosed as having cirrhosis and scheduled for shunt surgery, revealed a relatively small liver with reversed flow through the inferior mesenteric vein and a wide coronary vein to esophageal varices. Successful obliteration was performed, and shunt surgery was not undertaken. Transhepatic portography of the male patient who presented with diarrhea and abdominal pain and subsequently became jaundiced revealed retrograde flow of the contrast medium through the inferior mesenteric vein and coronary vein. Selective catheterization of the coronary vein gave a good demonstration of the esophageal varices. When the esophageal varices had been obliterated, it was decided not to perform shunt surgery.

9537 CERVICAL LYMPH-VENOUS SHUNT IN EXPERIMENTAL ASCITES AND IN PATIENTS WITH HEPATIC CIRRHOSIS. *(E.)* Donini, I.; Bresadola, F. (Gen. Surg., Surg. Ther. Clin. Inst., Univ. Ferrara, Italy). *Lymphology* 7(2):105-108, 1974.

The thoracic duct-jugular venous junction was examined in 10 mongrel dogs (15-20 kg) with ascites after experimental constriction of the supradiaphragmatic inferior vena cava. There was an increased pressure gradient across the thoracic duct-jugular vein junction and an increased resistance to thoracic duct lymph flow. After the thoracic duct was anastomosed to the external jugular vein, vascular resistance fell accompanied by an increase in thoracic duct lymph flow and a fall in the lymph-venous pressure gradient. Ascites disappeared. Based on these experimental findings, the thoracic duct-jugular venous junction was revised in 15 patients with hepatic cirrhosis with massive ascites intractable to medical treatment. After the operation, ascites improved in 3 patients (23%) and completely disappeared in 10 (77%) over the following 3-21 months. Two patients died: one of pneumonia, 30 days postoperative, and the other of gastrointestinal hemorrhage, 7 days postoperative. These findings support the notion that narrowing at the thoracic duct-jugular venous junction represents a restriction to maximal lymph flow and thereby an important factor in the pathogenesis of ascites in hepatic cirrhosis. Revising the junction through reanastomosis of the thoracic duct to the jugular vein potentiates lymph flow and relieves ascites without adversely affecting liver cell function.

9538 THE METABOLIC BASIS OF PORTASYSTEMIC ENCEPHALOPATHY AND THE EFFECT OF SELECTIVE VS NONSELECTIVE SHUNTS. *(E.)* Warren, W. D.; Rudman, D.; Millikan, W.; Galambos, J. T.; Salam, A. T.; Smith, III, R. B. (Emory Univ. Sch. Med., Atlanta, Ga.). *Ann. Surg.* 180(4):573-579, 1974.

The effects of selective and nonselective portacaval shunt procedures on nitrogen metabolism were assessed in 37 patients by studying the maximal rate of urea snythesis, ammonium chloride sensitivity and the clinical development of portasystemic encephalopathy. Of these, 18 were evaluated both before and after surgery. All patients had normal renal function and no ascites. Selective shunting did not significantly alter the maximal rate of urea synthesis following challenge with casein hydrolysate p.o. or crystalline amino acids (i.v.) whereas patients with nonselective shunts showed an increased rate (40 ± 4.21 mg urea N/hr/kg weight) compared to preoperative values (24.7 ± 4.51). Nonselective shunt procedures, unlike selective shunts, also adversely affected ammonium chloride tolerance (0.14 ± 0.02 g/kg weight maximal tolerated preoperative dose *versus* 0.06 ± 0.01 postoperative dose). Of 9 patients randomized for nonselective shunt, 5 developed postoperative encephalopathy compared to 1 of 9 patients treated by selective shunt. Overall, 85% of patients with encephalopathy had maximal rates of urea snythesis < 30 mg urea N/hr/kg weight. These data indicate that the selective shunt is clearly superior to the nonselective shunt with respect to protein metabolism. It also appears that patients with a marked restriction of urea synthesis preoperatively may be at high risk for developing postoperative encephalopathy.

9539 EMERGENCY ENDOSCOPY AFTER GASTROINTESTINAL HAEMORRHAGE IN 50 PATIENTS WITH PORTAL HYPERTENSION. *(E.)* Waldram, R; Davis, M.; Nunnerley, H.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Br. Med. J.* 4(5936):94-96, 1974.

Emergency endoscopy was performed in 50 patients with portal hypertension within 24 hr of a major episode of hematemesis or melena in an attempt to identify the bleeding site. All patients had esophageal varices; 11 patients also had gastric varices. One or more sources of bleeding were identified in 42 of the patients. Esophageal varices were the sole source of bleeding in only 16 cases with an additional 3 patients having bleeding esophageal varices in addition to another bleeding site. Bleeding from gastric varices was present in 11 patients. Acute erosive lesions of the esophageal, gastric and duedenal mucosa were the source of bleeding in 11 cases. Only 5 patients were bleeding from erosive gastric lesions, a finding at variance with previous studies. Gastric mucosal bleeding was no more common in 23 patients with alcoholic cirrhosis than in the entire group. Bleeding sites could not be determined in 8 patients either because of excessive blood being retained or because more than 1 lesion was present without any one being the obvious site.

9540 PREDICTION OF MORTALITY IN CIRRHOSIS OF THE LIVER.

(E.) Lecompte, Y.; Metreau, J. M.; Sancho, H. S.; Bismuth, H. (Paul Brousse Hosp., Villejuif, France). *Surg. Gynecol. Obstet.* 139(4):529-530, 1974.

The short-term mortality rate (1 month) of 136 patients with cirrhosis who were treated in a medicosurgical intensive care unit was studied to determine the prognostic value of 4 factors: gastrointestinal bleeding, encephalopathy, renal insufficiency, and coagulopathy. Based on the findings, 3 groups could be distinguished: 1) those with 0 or 1 factor (7.2 ± 6% mortality rate); 2) those with 2 factors (56.5 ± 20% mortality); and 3) those with 3 or 4 factors (100% ± 8% mortality). The prognostic value of gastrointestinal bleeding was studied separately and it was found that patients with only hemorrhage had a lower mortality rate (7%) than that of any other single factor (20%) although the difference was not significant. The results indicated that the presence of hemorrhage, encephalopathy, renal failure or coagulopathy alone in cirrhotic patients does not imply early death with certainty if they are the only serious signs. However, in this series all patients who presented with 3 or 4 factors died within 1 month. These patients are thus at high risk and are therefore candidates for hepatic transplantation even though such a procedure carries a high mortality rate.

9541 CIRRHOSIS AND MALIGNANT HEPATOMA IN α_1-ANTITRYPSIN DEFICIENCY.

(E.) Eriksson, S.; Hagerstrand, I. (Malmo Gen. Hosp., Sweden). *Acta Med. Scand.* 195(6):451-458, 1974.

Clinical and laboratory findings in 9 adults with both severe α_1-antitrypsin deficiency (Pi^{ZZ}) and non-alcoholic cirrhosis are presented. All patients were aged 50 yr or older at the time of diagnosis of cirrhosis which was rapidly progressive, terminating in coma or bleeding. Most patients presented with portal hypertension and ascites. Of 8 patients who died during the study, 6 had primary liver carcinoma (hepatocellular in 4 and cholangiocellular in 2). Hepatoma was suspected prior to death in only 1 patient. Histologically, all livers showed cirrhosis with prominent nodular regeneration. Cholestasis was not prominent. All livers contained typical periodic-acid-Schiff-positive inclusion bodies which were never seen within hepatoma cells. Emphysema was documented in 7 of the 9 patients and was clinically unrecognized, however, in 4. All but 1 patient had low serum albumin and hyper-γ-globulinemia with an unusually high immunoglobulin M level. Hepatitis-associated antigen was not detected and serum auto-antibodies were not present. Ceruloplasmin was slightly increased in most patients and α_1-antitrypsin deficiency was a prominent feature. It is estimated that the risk of cirrhosis in adults with the Pi^{ZZ} phenotype is about 10% and its pathogenesis remains obscure.

9542 CHANGES IN THE MORPHOLOGY AND HISTOCHEMISTRY OF PRETERMINAL DIGITAL CIRCULATION IN CIRRHOSIS. I.

(It.) Cantoni, L.; Curri, S. B.; Andreuzzi, P.; Samarani, O. (Maggiore Ca Granda Hosp., Milan, Italy). *Minerva Med.* 65(38/39):2248-2260, 1974.

Biopsies were taken from the tip of the left ring finger of 42 men and women, aged 36-67 yr, with chronic liver disease which was developing into cirrhosis. Nonspecific changes were found in the intermediate segment of type II, group B arteriovenous anastomoses in Bucciante's system of classification. Perisegmentary proliferation of the connective tissue was observed. The most important finding was areas of fibrinoid necrosis in the ground substance, indicating that connective tissue takes part in cirrhosis. These findings substantiate Villa's view that an angiodystrophic factor present in connective tissue is largely responsible for liver damage in cirrhosis. These changes are not limited to the liver, but may account for dehydration and lack of elasticity of the skin in cirrhotic patients, as well as capillary angectasia.

9543 USE OF L-DOPA IN THE TREATMENT OF HEPATIC COMA: CONSIDERATIONS AND PERSONAL CONTRIBUTION.

(Sp.) Ossorio Castellanos, C.; Noguera Hernando, E.; Isasia Munoz, T.; Aboy Martin, A.; Seonae, J. (Gran Hosp. Estado, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 43(5):563-672, 1974.

Case reports are presented for 6 patients (4 men and 2 women, aged 39-61 yr) with long histories of cirrhosis who were hospitalized with hepatic coma (grades I-IV). L-Dopa was generally given in doses of 5 g/day p.o. through a stomach tube until the patient recovered consciousness; the dose was then reduced to 1.5-3 g/day for 2 days. Total doses amounted to 5-32 g over periods of 1-6 days. Other treatment consisted of glucose infusions (6 cases), blood (2), glucose and potassium infusions (6), metoclopramide (4), vitamin K (6), and enemas (6). Response to therapy was excellent in 2 cases, good in 2, fair in 1, and nil in 1. Patients generally recovered consciousness later than others reported in the literature. This is attributed to their poor general condition, the presence of other conditions (e.g. dehydration and hypokalemia) affecting the outcome in some cases, and the generally poor prognosis (terminal cirrhosis, previous episodes of obnubilation, esophageal varices). Side effects consisted of vomiting (4 cases) which responded to metoclopramide and a possible rebound effect on the 2nd day in 1 case. The only change L-dopa produced was stimulation of consciousness; blood ammonia levels did not decrease and no changes occurred in blood and urine pictures, prothrombin time, total serum protein and serum protein fractions, serum transaminase activities, and pH. Four patients died, of gastrointestinal bleeding (2 cases), acute pulmonary edema (1 case), and hepatorenal syndrome (1 case).

9544 SEGMENTAL AND LOBAR ATROPHY OF THE LIVER. *(E.)* Ham, J. M. (Prince Henry Hosp., Sydney, Australia). *Surg. Gynecol. Obstet.* 139(6):840-844, 1974.

Case reports for 9 patients (4 men and 5 women, aged 32-70 yr) with segmental or lobar atrophy of the liver illustrate the clinical, roentgenological, and operative diagnostic problems that can arise in such patients. Presumed causes of atrophy were vascular or biliary obstruction, hepatocellular damage, or a combination of these factors. Final diagnoses included sclerosing cholangitis, intrahepatic tumors, hydatid disease, alcoholic liver diseases, acute hepatic necrosis, and cirrhosis. In none of the 5 patients who had liver scans was the correct diagnosis made, and angiograms were correct in only 1 of 3 cases. Macroscopic features at operation were similar. The segment or lobe was well demarcated from other liver tissue, markedly shrunken, firm, and pink; the liver capsule was usually wrinkled. Microscopic features were also similar and included collapse of the reticulin framework, disappearance of hepatocytes, proliferation of small bile ducts, and fibrosis in portal tracts together with an acute inflammatory cell infiltrate. At operation, the most likely cause of atrophy can be decided from the appearance of the remainder of the liver. Biliary or vascular obstruction is probably present if the remainder is normal in appearance, whereas if the remainder is cirrhotic and the extrahepatic biliary system normal, postnecrotic cirrhosis can be suspected. Operative cholangiography, including roentgenograms of the intrahepatic ducts, may show or malignant stricture or to intrahepatic stones. If atrophy is due to benign or malignant stricture or to hydatid disease, resection of the atrophic segment or lobe, together with the causative lesion, may be indicated. Alternatively, relief of ductal obstruction may be achieved by anastomosis of the duct to a jejunal loop.

9545 METABOLIC CLEARANCE OF HEXOBARBITAL IN PATIENTS WITH ACUTE HEPATITIS AND CIRRHOSIS OF THE LIVER. *(E.)* Richter, E.; Breimer, D. D.; Zilly, W.; Keller, B.; Brachtel, D. (Dept. Intern. Med., Univ. Wurzburg, Germany). *Digestion* 10(4-5):377, 1974.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

9577 EFFECT OF GLYCEROPHOSPHATE ON LITHOGENIC BILE. A NEW APPROACH TO TREATMENT OF CHOLELITHIASIS. *(E.)* Linscheer, W. G.; Raheja, K. L. (VA Hosp., Syracuse, N.Y.). *Lancet* 2(7880):551-553, 1974.

The effect of short-term p.o. administration of β-glycerophosphate on the bile composition of 10 patients (3 female and 7 male, aged 44-64 yr) with lithogenic bile was studied. Nine of the patients had gallstones. Previous studies in animals showed a twofold increase of bile-phospholipids when glycerophosphate, a precursor of phospholipids, was incorporated in the diet. Fasting hepatic and gallbladder bile before and after treatment with the β-glycerophosphate (6 g p.o./day for 6 days) was analyzed for molar ratios of cholesterol, total bile salts, and total phospholipids. Duodenal intubation was performed following an overnight fast using a special tube with a steerable tip. Two hepatic bile samples were collected by hydrostatic pressure, and gallbladder emptying was accomplished by injection of 50% magnesium sulfate solution (40 ml) through the distal lumen. Two samples of gallbladder bile were then collected through the proximal lumen. β-Glycerophosphate treatment resulted in a lowering of the molar ratios of cholesterol to total bile salts and total phospholipids in 9 of 10 patients. This observation was confirmed by plotting the molar percentages on triangular coordinates. Cholesterol concentrations did not appear to change, though increases in phospholipid and bile salt concentrations were observed. The composition of the gallbladder bile did not change. An evaluation of β-glycerophosphate as a potential new therapeutic agent for dissolution of cholesterol gallstones in man appears indicated.

9578 EXTRAHEPATIC BILIARY ATRESIA. THE FREQUENCY OF POTENTIALLY OPERABLE CASES. *(E.* Danks, D. M.; Campbell, P. E.; Clarke, A. M.; Jones, P. G.; Solomon, J. R. (Roy. Children's Hosp., Melbourne, Australia). *Am. J. Dis. Child.* 128(5):684-686, 1974.

The frequency of potentially operable cases of extrahepatic biliary atresia is illustrated in an analysis of 50 patients (ages 3 days to 5 months) seen over an 18-yr period, 24 of whom were found to be potentially operable. Six of 17 patients in whom no patent ducts were found and on whom blind anastomosis was not performed eventually proved to have potentially operable lesions. Two of these patients showed postoperative bile drainage from the drain tube along with a clearing of jaundice; 1 is still alive at 6.5 yr, though she has biliary cirrhosis. The remaining 15 patients drained no bile after operation and subsequently died of liver failure. Patent bile ducts were demonstrated proximal to an atresic segment in 4 patients (3 females and 1 male) who underwent anastomosis. Two of the patients died of chronic cholangitis postoperatively, while 1 (the male) appears to have been cured (normal liver biopsy at 2 yr of age). The other patient (female) is alive and clinically well at the age of 7.5 yr, although she has biliary cirrhosis. Among 8 patients in the series on whom blind portoenterostomy was performed (Roux-en-Y technique in 2 cases and cutaneous bile enterostomy using an isolated segment of small bowel in 6 cases), bile flow sufficient to clear the jaundice occurred in 6. In a 7th patient, 90 ml of bile drained each day, but the jaundice had not completely cleared. Each of the 7 suffered several attacks of cholangitis, although 3 of these babies are currently progressing such that cure seems possible. An 8th patient drained no bile and died at 4 months of age. The findings to date indicate that 40-50% of all babies with extrahepatic bile duct obstruction must be regarded as having potentially operable lesions.

9579 SCLEROSING CHOLANGITIS AND ULCERATIVE COLITIS: AN INTERESTING CHOLANGIOTOMOGRAPHIC SIGN. *(E.)* Bunao, R. M.; Thomas, J. M.; Weaver, D. R.; Littleton, J. T. (no affil.). *Guthrie Bull.* 44(2):83-91, 1974.

An intravenous cholangiotomogram, together with other clinical and laboratory findings, was used to make a preoperative differential diagnosis of pericholangitis and sclerosing cholangitis, confirmed at laparotomy, in a 33-yr-old man with ulcerative colitis and an associated hepatobiliary complication resulting in secondary biliary cirrhosis. The patient presented with a 2 month history of painless, pruritic jaundice and a 15 yr history of colitis. Rectal biopsy confirmed sigmoidoscopic findings of chronic ulcerative colitis, and a percutaneous liver biopsy showed histologic features of subacute hepatitis. An intravenous cholangiotomogram done at a bilirubin level of 3.5 mg% showed a faint visualization of the intrahepatic and common bile ducts with non-visualization of the gallbladder, interpreted as representing periductal edema of pericholangitis and/or sclerosing cholangitis. Laparotomy, performed because of increasing icterus (total bilirubin of 13 mg% with a direct reading fraction of 6 mg%) and persistent serum alkaline phosphatase elevation (400 U/dl), confirmed the diagnosis. After undergoing an uneventful cholecystoduodenostomy and choledochostomy, the patient suffered a massive gastrointestinal hemorrhage 1.5 yr later and died in hepatic coma. Autopsy findings showed macronodular cirrhosis consistent with the biliary type and associated with acute pancreatitis, quiescent chronic ulcerative colitis, biliary nephrosis, splenomegaly, esophageal varices, ascites, anasarca, and gastrointestinal hemorrhage. The radiolucent halo observed along the margins of the opacified segments of the intrahepatic and common bile ducts during the preoperative intravenous cholangiotomogram appears to merit further corroboration as a roentgenological indication of pericholangitis or sclerosing cholangitis.

9580 BILIARY ATRESIA: NEW CONCEPTS OF PATHOLOGY, DIAGNOSIS, AND MANAGEMENT. *(E.)* Bill, A. H.; Brennom, W. S.; Huseby, T. L. (Childrens Orthopedic Hosp. Med. Ctr., Seattle, Wash.). *Arch. Surg.* 109(3):367-369, 1974.

A Japanese surgical technique (Kasai operation) for correcting biliary atresia in infants with no patent extrahepatic ducts is described. Assuming that a proximal duct suitable for anastomosis to the small bowel is not present, mounds of tissue (just anterior to the portal vein where the extrahepatic ducts ordinarily emerge from the liver) which contain the fibrosed remnants of the extrahepatic ducts are dissected off within a 1-cm diameter area (2 or 3 mm into the liver). Bleeding from the liver is controlled by pressure (never by cautery). A small bowel anastomosis is then made around the periphery of this raw area to the liver capsule and to the anterior wall of the portal vein posteriorly. A double Roux-en-Y anastomosis that includes an external vent is performed since a simple Roux-en-Y anastomosis does not prevent ascending cholangitis. Of 116 Japanese cases operated on before 3 months of age, 42% were found without jaundice 1 year or more after surgery. Observations of 8 primary anastomoses of the same type in the United States for patients under 3 months of age indicate 4 cases without jaundice over a year after surgery. Bile flow was demonstrated in 3 of 4 less than a year postoperatively. The livers in all the cases are still enlarged and show other signs of cirrhosis, though Japanese experience suggests that these livers will continue to improve. The patient should be operated on before 3 months of age. If the ducts are less than 200 μ in diameter, adequate excretion of bile is unlikely. The occurrence of ascending cholangitis after bile flow establishment must be guarded against by the immediate use of antibiotics when unexplained fever appears.

9581 EPIDURAL ANALGESIA FOLLOWING CHOLECYSTECTOMY. *(E.)* Addison, N. V.; Brear, F. A.; Budd, K.; Whittaker, M. (Roy. Infirm., Bradford, England). *Br. J. Surg.* 61(10):850-852, 1974.

The postoperative analgesic effectiveness of epidural bupivacaine (Marcain) versus i.m. pethidine administration was assessed in 50 patients (1:3 male to female ratio) undergoing cholecystectomy. One group of 25 received 6 ml of bupivacaine postoperatively (*via* epidural catheter) followed by an additional 6 ml when pain was reexperienced, while the other group of 25 received a weight-related dose (i.m.) of pethidine postoperatively. Postoperative pain was assessed with the visual linear analogue method. Adequate analgesia was produced in 20% more patients receiving epidural analgesia than those receiving i.m. pethidine. Incidence of postoperative pulmonary infection in the epidural group was 4% as compared to a 20% incidence in the pethidine group. Complications considered to be directly due to the epidural technique included: acute postoperative retention of urine (3 patients); headaches and dizziness after the additional dosage of bupivacaine (2); profound hypotension (1 patient, 1 occurrence only); and severe pain at the site of catheter insertion necessitating catheter removal (1). Two patients complained that analgesia duration was short (as little as 2 hr). Epidural analgesia appears to be more effective than i.m. pethidine administration in reducing both postoperative pain and incidence of pulmonary infection. The small but significant number of complications arising from the procedure and the additional time it requires may preclude wider adoption of the method; it should, however, be considered for high-risk patients.

9582 OCCURRENCE OF CHOLESTEROL CRYSTALS IN HUMAN BILE. *(E.)* van der Linden, W.; Nakayama, F. (Central Hosp., Ostersund, Sweden). *Gut* 15(8):630-635, 1974.

The occurrence of cholesterol crystals in the gallbladder and hepatic bile of 20 consecutive gallstone patients with functioning gallbladders, in T-tube drain bile from 10 consecutive choledochostomy patients with reestablished enterohepatic circulation, and in hepatic bile from gallstone patients with visualized *versus* non-visualized gallbladders (cholecystography) was studied. In the 1st group, the occurrence of cholesterol crystals rose sharply with the number of stones in the gallbladder. Gallbladder bile more often contained cholesterol crystals than hepatic bile for a given individual. Crystals were absent from the hepatic bile of the 10 T-tube patients; during operation crystals had been present in the hepatic bile of 5. Cholesterol crystals in gallstone patients whose gallbladder was visualized by cholecystography appeared more often than in patients with gallbladders not visualized by cholecystography; in the latter patients crystals tended to disappear after prolonged fasting (more than 12 hr). The composition of bile with cholesterol crystals did not differ significantly from that of bile without crystals. More chenodeoxycholic acid was observed in the bile from patients with non-functioning gallbladders than those with functioning gallbladders.

9583 HEMOBILIA PSEUDOANEURYSM IN THE GASTRODUODENAL ARTERY FOLLOWING CHOLEDOCHOTOMIA. A CASE REPORT. *(E.)* Ekeland, A.; Ofstad, E.; Stiris, G. (Aker Hosp., Oslo, Norway). *Acta Chir. Scand.* 140(5):422-427, 1974.

A case of hemobilia pseudoaneurysm in the gastroduodenal artery of a 52-yr-old male who underwent cholecystectomy and removal of 2 stones from the common bile duct is reported. The patient felt dizzy, started to bleed from the T-tube inserted during his previous operation, and went into shock on the 10th day following the operation; he also developed an obstructive jaundice (bilirubin 11.5 mg%). Aortography showed an aneurysm in the gastroduodenal artery. A pulsating aneurysm was located between the T-tube and the duodenum, right over the common bile duct, during a subsequent operation. A catgut thread was found close to the aneurysmal wall. The thread had been used to close the incision in the common bile duct during the first operation. There was also a hole in the aneurysm and a corresponding hole in the common bile duct, suggesting that the arterial pulsation in the aneurysm had caused pressure necrosis with perforation and leakage of blood into the biliary tree. The common bile duct was occluded by blood clots, causing the patient's jaundice. The clots were removed, and a cholangiogram taken through a new T-tube passed into the perforation in the common bile duct was clear. Recovery after the operation was uneventful. Histological examination of the aneurysm showed that it was a false aneurysm; a homogenous area consisting of catgut was found quite near the perforation opening. The cause of the false aneurysm and the hemobilia appeared to be a catgut suture which had been accidentally placed in the wall of the gastroduodenal artery during closure of the common bile duct.

9584 TRANSDUODENAL SPHINCTEROPLASTY. ITS USE IN THE TREATMENT OF LITHIASIS AND BENIGN OBSTRUCTION OF THE COMMON DUCT. *(E.)* Stefanini, P. Carboni, M.; Patrassi, N.; De Bernardinis, G.; Negro P.; Loriga, P. (Univ. Rome Med. Sch., Italy). *Am. Surg.* 128(5):672-677, 1974.

Immediate and long-term results of transduodenal sphincteroplasty in 712 patients with either lithias or benign obstruction of the common bile duct are reported to illustrate the advantages of sphincteroplasty over choledochoduodenostomy in treating such conditions. Common duct lithiasis accounted for 31 cases, while secondary papillitis, primary papillit and chronic pancreatitis accounted for 182, 34, and 12 cases, resp. There were 7 deaths in the 712 sphincteroplasties, although death was related to surgery in only 1 patient who died of acute pancreatitis. Other mortalities were related to biliary cirrhosis or postoperative complications normally seen in a series of this size. The overall morbidi was 2% and consisted principally of hyperamylasemia bleeding, wound infection, and pneumonitis. Long-term follow-up (55 months average) of 542 patients available for study revealed excellent or good results for 70.5% (no hepatic, biliary, or pancreatic symptoms were present). Complaints of mild tempora pain in the hepatic or pancreatic region and digestive troubles were seen in 26.5%. Symptoms unrelieved by sphincteroplasty persisted in 16 patients recurrent or residual stones (9); stenosis of the sphincter of Oddi and cholangitis (5); ascending cholangitis (1); and persistent pancreatic pain and common bile duct restricture (1). Compared with choledochoduodenostomy, sphincteroplasty avoids the hazards of the sump syndrome and of ascending cholangitis by reflux of intestinal contents into the common duct. A high incidence of postoperative pancreatitis was not observed in patients undergoing sphincteroplasty.

9585 BACTERIA AND BILIARY TRACT DISEASE. *(E.)* Goswitz, J. T. (Med. Coll. Wisconsin, Milwaukee). *Am. J. Surg.* 128(5):644-646, 1974.

Bile specimens for culture were taken from the gallbladder of 118 consecutive patients (25 male and 9 female, most falling between 21-70 yr of age) with disease originating in and involving only the bili ract, to identify those patients who are most likely o have infected bile. The first 50 patients also ad cultures of bile taken from the common bile duct. he incidence of infected bile was only 5.3% for outine cases of chronic cholecystitis with choleithiasis and without complicating ductal stones or cute inflammation. However, the incidence of inected bile increased to 65% for patients with such omplications as acute inflammation or migration of stone from the gallbladder. An acute process, aking the form either of an inflammatory reaction r an obstruction in the ductal system by a galltone, appears essential for the development of inected bile. Coliform organisms predominated among he organisms cultured. Cephalothin was the i.v. ntibiotic of choice. Chloramphenicol can be started .o. if the patient is able to tolerate feedings beore the results of sensitivity studies are returned.

586 BILIARY ATRESIA AND OTHER STRUCTURAL ANOMALIES IN THE CONGENITAL POLYSPLENIA SYNROME. *(E.)* Chandra, R. S. (Children's Hosp. Natl. ed. Ctr., Washington, D.C.). *J. Pediatr.* 85(5): 49-655, 1974.

linical and pathologic findings from autopsy or urgical exploration are presented for 10 children (6 females and 4 males, age 3 days to 6 yr) with ongenital polysplenia syndrome; a subgroup of 5 hildren with biliary atresia and other noncardiac nomalies is examined in detail. Although anomalies f the cardiovascular system usually dominate the linical picture of congenital polysplenia syndrome, 4 of the 5 patients with extrahepatic biliary atresia nd biliary cirrhosis had no associated cardiac anomalies. Liver symmetry was present in 3, and malrotation of the gastrointestinal tract was common to all patients with biliary atresia. Abdominal situs inversus was present in 4 of 10 patients examined, 3 of whom had biliary atresia. Other anomalies specific to the group with biliary atresia were: a bilobed right lung (2 cases); a persistent left superior vena cava to the coronary sinus (1); a preduodenal portal vein (1); and the combination of tracheoesophageal fistula associated with esophageal atresia, malformed thoracic vertabrae, right renal agenesis, and pulmonary levo-isomerism (1). The findings indicate that biliary, respiratory, and intestinal abnormalities are also components of the polysplenia syndrome.

9587 LYSOLECITHIN AND LECITHIN IN THE GALLBLADDER WALL AND BILE: THEIR POSSIBLE ROLES IN THE PATHOGENESIS OF ACUTE CHOLECYSTITIS. *(E.)* Sjodahl, R.; Wetterfors, J. (Univ. Hosp., Linkoping, Sweden). *Scand. J. Gastroenterol.* 9(6):519-525, 1974.

Lecithin and lysolecithin contents of gallbladder bile and wall were analyzed in 28 patients (17 females and 11 males, average age 50 yr) who underwent cholecystectomy for acute or chronic cholecystitis. The patients were divided into 3 groups: chronic cholecystitis with normally colored bile (11 patients); chronic cholecystitis with discolored bile (7); and acute cholecystitis (10). The absolute concentration of lecithin in gallbladder bile from groups 2 and 3 was considerably lower than that for group 1, while the lysolecithin bile concentration was about the same in each group. Lecithin as a percentage of total bile phospholipids in group 2 and 3 patients was 71.5 ± 17.3 and 56.4 ± 8.6 as compared to 97.9 ± 0.6 for patients in group 1. Lysolecithin percentages for chronic, chronic discolored, and acute cases were 0.3 ± 0.1, 4.5 ± 1.9, and 5.5 ± 4.1, resp. Total amount of phospholipids in the latter 2 groups was considerably lower than for normals or group 1 cases. Lysolecithin in plasma was lower than normal in absolute and relative amounts in about 2/3 of the patients with acute cholecystitis, with the mean value (% total phospholipids) being 2.9 ± 1.7 and the absolute concentration being 0.09 ± 0.06 μM/ml as compared to a normal value of 0.20 ± 0.01 μM/ml. Bilirubin concentration in the gallbladder bile of patients in groups 2 and 3 were also much lower (1 or 2 orders of magnitude) than for chronic patients. The increased lysolecithin/lecithin ratio in group 2 and 3 patients indicates that lysolecithin may be locally formed from lecithin. Lysolecithin is not accumulated in the gallbladder wall. The lowered bilirubin concentrations observed 4 days after the beginning of acute cholecystitis supports the importance of the occluded gallbladder in the pathogenesis of acute cholecystitis and is an expression of an increased resorption of bilirubin through the mucous membrane of the gallbladder.

9588 PARTIAL RESECTION OF THE LIVER FOR PRIMARY CHOLANGIOCARCINOMA. PRESENTATION OF A SUCCESSFUL CASE. *(E.)* Sanguily, J.; Calderin, V. O. (Pan American Hosp., Miami, Fla.). *Am. J. Surg.* 128(5):603-607, 1974.

A case of primary cholangiocarcinoma of the liver, treated surgically by wedge resection of the right lobe of the liver, is described. The patient, a 61-yr-old woman, presented with a movable, nontender mass in the upper right quadrant which had been present for 8 months but had produced no symptoms. Physical examination gave essentially negative results. A liver scan revealed a rounded space-occupying lesion with decreased activity present in the anteroinferior aspect of the right lobe. Exploratory laparotomy showed a large whitish tumor with a granular surface, not resembling liver tissue, in the right lobe and just above the gallbladder. The tumor had not adhered to any other abdominal organ, and no signs of an acute inflammatory process were observed. The gallbladder was firmly attached to the tumor which was deeply imbedded therein. The gallbladder was freed from below by doubly ligating the cystic duct and cystic artery with 2-0 black silk. The full thickness of the liver was transected with an electric knife, removing a considerable segment of the right lobe along with a large area of tissue beyond the gallbladder within the normal liver parenchyma. The remaining raw area of the liver tissue appeared normal. Its entire surface was covered with the omentum and sutured with interrupted stitches of 2-0 black silk. This epiploplasty was considered superior to the use of hemostatic material which could have created an inflammatory foreign body reaction. A frozen section study of the tumor indicated cancer of ductal origin. The patient remains in excellent health 2.5 yr after surgery.

9589 RECURRENT PYOGENIC CHOLANGITIS IN CHINESE IMMIGRANTS.

(E.) Ho, C. S.; Wesson, D. E. (Toronto Gen. Hosp., Canada). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):368-374, 1974.

Findings from pre-operative and operative cholangiographic studies, surgical exploration, laboratory tests, and liver biopsies are presented for 5 Chinese immigrant patients (3 women and 2 men, ages 41-84 yr) with recurrent pyogenic cholangitis (also known as cholangiohepatitis, oriental cholangiohepatitis, and Hong Kong disease). The disease usually occurs in young adults (30-40 yr), with both sexes being equally affected. Clinically, the disease is characterized by recurrent attacks of right upper quadrant pain, fever, chills, and jaundice. Laboratory findings reflect the clinical features of sepsis and obstructive jaundice. Leukocytosis is usually present. Serum bilirubin and alkaline phosphatase are both elevated. Cultures of bile obtained at operation showed *Escherichia coli* infection in most patients. Roentgenologic findings were usually unrevealing, though in 2 cases reported the condition was diagnosed with pre-operative cholangiographic findings. Typical T-tube cholangiographic findings are: a decrease in arborization of intrahepatic radicals; an abnormal branching pattern (normal branching angles are distorted); asymmetric changes in the bile ducts (dilatation throughout or proximal dilatation with rapid tapering towards the periphery); the presence of radiolucent stones anywhere in the biliary tree; and a dilated common bile duct (3-4 cm in diameter). The following conditions produce changes similar in some respects to recurrent pyogenic cholangitis and should be considered in differential diagnosis: extrahepatic obstruction; sclerosing cholangitis; and Caroli's disease.

9590 RELIEF OF OBSTRUCTIVE JAUNDICE THROUGH PERCUTANEOUS TRANSHEPATIC CATHETER - A NEW THERAPEUTIC METHOD.

(E.) Molnar, W.; Stockum, A. E. (Univ. Hosp., Ohio State Univ., Columbus). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 122(2):356-367, 1974.

The nonsurgical decompression of biliary obstructions with a percutaneous transhepatic catheter for relief of obstructive jaundice is illustrated in summaries of 11 patients (6 females and 5 males, ages 23-80 yr) suffering from either benign postoperative strictures or malignant obstructive lesions. In 2 patients with benign stricture, the transhepatic drainage tube was inserted to improve the patients' conditions prior to contemplated surgical repair, while the condition of the biliary system in the remaining 9 patients precluded further surgical intervention. Indications for treating benign strictures by transhepatic biliary decompression are: postoperative biliary duct stricture with complications; restenosed hepatoduodenal or jejunal anastomosis; and obstruction and intrahepatic stones. Indications for using the method in cases of malignant tumors are: intrahepatic obstruction involving either primary biliary tumors or single hepatic metastasis and extrahepatic obstruction involving recurrent primary biliary tumor recurrent pancreatic tumor; or single porta hepatis metastasis. Hepatorenal failure rules out intrahepatic positioning of a tube for either external or internal drainage in patients with malignant obstruction. Renal dialysis should be initiated before placement of the transhepatic tube in patients with hepatorenal failure and biliary obstruction due to benign stricture. Antibiotic coverage before and after the procedure is mandatory in patients with pending or existing renal failure. Significant delays in clotting mechanisms should be corrected before transhepatic insertion of the drainage tube. The value of transhepatic biliary decompression is questionable in patients with sclerosing cholangitis because of the numerous obstructions within the biliary system.

9591 THE TERMINATION OF THE COMMON BILE DUCT.

(E.) Keddie, N. C.; Taylor, A. W.; Sykes, P. A. (Roy. Infirm., Manchester, England). *Br. J. Surg.* 61(8):623-625, 1974.

Operative cholangiography revealed abnormal terminations of the common bile duct in 23% of 120 patients with biliary tract disease. In 13 of the 27 anomalous terminations observed, the termination was at the junction of the 2nd and 3rd parts of the duodenum while termination in another 13 patients was in the 3rd part of the duodenum at a point 2 cm distal to the junction of the 2nd and 3rd parts. The common bile duct of 1 patient joined the distal end of the 3rd part of the duodenum. Post-operative T-tube cholangiography of 10 patients with anomalous terminations was conducted to investigate whether the position of the ampulla of Vater varies during duodenal peristalsis. No ampullary movement was seen in 3 patients, and no conclusions were reached in the remaining 7 since the radiocontrast material failed to outline the distal part of the common bile duct during peristalsis. Terminations at the junction of the 2nd and 3rd parts as well as terminations in the proximal 2 cm of the 3rd part of the duodenum should be surgically accessible through a standard duodenotomy. Difficulty is only anticipated in the rare instances of termination in the distal portion of the 3rd part of the duodenum.

9592 JUVENILE CHOLELITHIASIS.

(Sp.) Rodriguez Cuartero, A.; Morata Garcia, F.; Pelaez Redondo, J. (San Cecilio Clin. Hosp., Granada, Spain *Rev. Esp. Enferm. Apar. Dig.* 43(5):529-538, 1974.

Of 600 cases of cholelithiasis, 3 were diagnosed in girls less than 20 yr old. Two patients were 16 yr old and the other was 19 yr old. All 3 patients had histories of biliary colic which, in 1 case, dated back 10 yr; the other 2 patients had 1-yr histories. Episodes of colic were accompanied by nausea and vomiting of bile in all 3 cases. No changes in bilirubin or lipid metabolism were found in any of these 3 patients. Cholelithiasis was diagnosed by oral cholangiography in all 3 patients. At surgery, more than 100 stones were found in the gallbladder of one patient and 45 stones in the other; the remaining patient refused surgery.

9593 SYNDROME OF INCOMPLETE BILE DUCT OBSTRUCTION IN CHOLECYSTECTOMIZED PATIENTS. *(Cz.)* Keclik, M.; Huslarova, A.; Horacek, F. (Polyclin. Fac., Charles Univ., Prague, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(1):31-36, 1974.

Clinical and surgical findings were analyzed for 98 cholecystectomized patients who later developed cholestasis and had to be reoperated. At the first operation, 21 patients had choledochoduodenostomies (group 1) and 77 did not (group 2). Since only about 1/2 of these patients developed jaundice, diagnoses were difficult to make; fully 1/3 had only simple attacks of pain. By using i.v. cholangiography, stones were detected in only 2/3 of those who had them at surgery. Serum alkaline phosphatase values were elevated (higher than 13.5 King-Armstrong U) in 1/2 of the patients. Measurements of the width of the bile duct revealed dilatation (widths greater than 16 mm) in about 1/2 of the patients examined and ruled out obstruction in only 5.5%. Caroli's BSP time was positive (longer than 24 min) in 1/4 of the patients and negative in only 8%; no difference was found between patients with and without stones. At reoperation of patients in group (1), 17 had anastomotic stenosis, 2 had extrahepatic obstruction, and 2 had pancreatic carcinoma. Amoung the patients in group (2), choledocholithiasis was diagnosed in 47 cases (61%) and was associated with papillary stenosis or pancreatitis in 29 cases. Biliary or papillary stenosis was detected in 18 cases, pancreatic disease in 6 cases, biliary dilatation with no evidence of obstruction in 4 cases, and biliary trauma in 5.2%; the cause of cholestasis was not clear in 2 cases. One of these patients had cirrhosis associated, after cholecystectomy, with symptoms of cholestasis and later passed stones in the stools. The second patient had chronic hepatitis with an atypical pain syndrome.

9594 ASSOCIATION BETWEEN CHOLELITHIASIS AND CROHN'S DISEASE. *(Cz.)* Dvorakova, H.; Setka, J.; Balas, V.; Niederle, B. (Fac. Gen. Med., Charles Univ., Prague, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(1):46-51, 1974.

Of 22 patients with terminal ileitis, 7 (6 women and 1 man, aged 32-61 yr) also had cholelithiasis. In contrast, only 1 of 126 patients with ulcerative colitis had cholelithiasis. Of these 7 patients, 5 developed intestinal symptoms first, 1 had symptoms of cholelithiasis first, and 1 developed symptoms of both diseases simultaneously. Intestinal symptoms were clearly evident in all patients and consisted of diarrhea (5 cases), pain in the periumbilical or right mesogastric regions (5), and disturbances in intestinal transit (3). Only 2 patients, however, had typical biliary colic. Three patients were mistakenly suspected of gynecological disease and 1 was thought to have postcholecystectomy syndrome. The diagnosis of terminal ileitis was missed in 3 cases. Two of these 7 patients were monozygotic twins. The best results were obtained by simultaneous surgical treatment for both diseases, i.e. cholecystectomy, resection of the terminal ileum, hemicolectomy, or anastomosis between the ileum and transverse colon. Cholelithiasis was treated conservatively in 2 patients who had undergone surgery for terminal ileitis 12 yr before. One patient died of peritoneal abscesses 10 days after surgery for terminal ileitis. It is suggested that terminal ileitis may cause cholelithiasis due to impairment of the enterohepatic circulation of bile salts which, under normal conditions, help prevent precipitation of cholesterol from the bile. This impairment of bile salt absorption is more pronounced in patients who have undergone resection of the terminal ileum, where active transport of bile acids occurs, than in patients who have not undergone surgery for terminal ileitis.

9619 THE SMALL INTESTINAL LESION INDUCED BY HAWAII AGENT ACUTE INFECTIOUS NONBACTERIAL GASTROENTERITIS. *(E.)* Schreiber, D. S.; Blacklow, N. R.; Trier, J. S. (Boston Univ. Med. Ctr., Mass.). *J. Infect. Dis.* 129(6):705-708, 1974.

The morphology of the proximal small intestinal mucosa of 6 healthy adult male volunteers receiving an inoculum of Hawaii agent, which produces nonbacterial gastroenteritis, was studied by light microscopy. Two volunteers developed clinical gastroenteritis and an intestinal mucosal lesion with altered mucosal architecture, mucosal inflammation, and abnormal-appearing absorptive cells. This lesion was indistinguishable from the intestinal lesion demonstrated previously in volunteers who had ingested Norwalk agent, another agent known to produce nonbacterial gastroenteritis. In addition 2 of 4 asymptomatic volunteers developed the typical mucosal lesion. The 3rd asymptomatic volunteer developed late, mild, nonspecific histologic changes. Biopsies from the 4th asymptomatic volunteer remained normal. These findings indicate that Hawaii agent, although apparently immunologically distinct from Norwalk agent, produces an identical lesion of the proximal small intestine. This suggests that this lesion is characteristic of viral gastroenteritis and not restricted to disease produced by one specific infectious inoculum.

9620 UPPER GASTROINTESTINAL BLEEDING CAUSED BY VASCULAR FISTULAS. *(Sp.)* Perez Carnero, A.; Mino Fugarolas, G.; Hita Perez, J.; Muro, J.; Diago Ferrero, A. (La Paz Munic. Sanit., Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 44(1):1-8, 1974.

Case reports are presented for 5 patients who had gastrointestinal bleeding due to vascular fistulas. Of 2 esophagoaortic fistulas, one was caused by an esophageal ulcer, 4 cm in diameter, communicating with the aorta; this ulcer is attributed to irritation caused by a fishbone. The second resulted from an esophageal carcinoma ulcerating into the mediastinum and infiltrating the wall of the aorta. Both patients died after massive gastrointestinal hemorrhages. Three months after tonsillectomy, a 9-yr-old girl died of a ruptured aneurysm of the left internal carotid artery which opened into the pharyngeal cavity. A 58-yr-old man with a 2-yr history of repeated hematemesis and melena died of massive bleeding after surgery for a ruptured aneurysm of the gastroduodenal artery. Autopsy showed a retropancreatic, juxtarenal hematoma associated with the aneurysm which communicated with the pancreatic duct. A 31-yr-old man developed epigastric pain radiating to the right hypochondrium, progressive jaundice, hematemesis, and melena 14 days after a traffic accident in which his fibula and acetabulum were fractured. Surgery showed ruptured hepatic blood vessels which communicated with the biliary tract.

GENERAL

Parasitology

666 HOOKWORM ENTEROPATHY. *(E.)* Falaiye, J. M.; Oladapo, J. M.; Wali, S. S. (Coll. Ied., Univ. Lagos, Nigeria). *J. Trop. Med. Hyg.* 77(9):211-214, 1974.

Histologic and functional appraisal of 12 patients with hookworm disease showed subtotal villous atrophy in 3 and subnormal xylose absorption in 8. There was no relation between the load of hookworm infestation and the xylose malabsorption or the severity of jejunal mucosal damage. Seven of the 8 patients with xylose malabsorption were moderately to severely anemic, but the anemia showed no correlation with jejunal histologic abnormalities. Hypoalbuminemia in 10 patients was associated with subnormal xylose absorption in 8, and all 3 patients with subtotal villous atrophy were severely hypoalbuminemic. Protein deficiency is apparently the basis for intestinal abnormalities in hookworm disease.

9667 ARRESTED DEVELOPMENT IN *Ancylostoma duodenale*: COURSE OF A SELF-INDUCED INFECTION IN MAN.

(E.) Nawalinksi, T. A.; Schade, G. A. (Sch. Hyg. Pub. Hlth., Johns Hopkins Univ., Baltimore, Md.). *Am. J. Trop. Med. Hyg.* 23(5):895-898, 1974.

The course of s self-induced infection with about 100 *Ancylostoma duodenale* larvae was followed by twice-weekly blood and stool examinations. After a small initial increase (511 to 779/mm^3), no further change in eosinophil counts occurred until week 33 when they began to increase sharply. Eggs appeared in stools 7 weeks later, after 5-6 times the normal prepatent period; the total eosinophil count at this time was 5262/mm^3. The mean egg count for the 1st week of patency was 262 eggs/g feces. This rose to 870 eggs/g feces for the 14th and 15th weeks of patency (weeks 54 and 55 postinfection). At weeks 75 and 76 postinfection, the egg count was 2575 eggs/g feces. Blood cell counts at week 78 showed 2851 eosinophils/mm.^{3} Apparently a strain of *A. duodenale* exists which either has an inherent, abnormally long prepatent period or a prepatent period susceptible to change, depending on the environmental conditions experienced by the free-living larvae. In either case, the 3rd-stage larvae probably enter a hypobiotic state within the host which lasts for about 8 months.

9668 SCHISTOSOMAL DISEASE OF THE COLON: A REVERSIBLE FORM OF POLYPOSIS.

(E.) Nebel, O. T.; El Masry, N. A.; Castell, D. O.; Farid, Z.; Fornes, M. F.; Sparks, H. A. (Naval Reg. Med. Ctr., San Diego, Calif.). *Gastroenterology* 64(5):939-943, 1974.

The effect of niridazol therapy (25 mg/kg/day for 10 days) in 15 patients with schiostosmal colonic polyposis was evaluated by direct visual inspection with the fiberoptic colonoscope and by biopsy. Patients were seen 3, 6, and 12 months after treatment. Pretreatment evaluation included physical examination, laboratory studies, stool parasitology, colonoscopy, and colon biopsy. Pretreatment anemia, present in all patients, was corrected by 3 months. Serum albumin, decreased in 11 patients, rose to normal levels by 12 months. Stool and urine were negative for schistosoma eggs (*Schistosoma mansoni* and *Schistosoma haematbium*) by 3 months. At 12 months, 4 patients showed complete resolution of polyposis and the remainder showed marked improvement in polyp size, friability, and number. In addition, all 12-month post-treatment biopsies were negative for viable eggs and permanent sections of colonic mucosal biopsies showed no histologic abnormalities. The results support the efficacy of medical treatment of schistosomal polyposis and indicate that polyposis may be a reversible lesion.

9669 THE EFFECT OF TINIDAZOL IN AMOEBIC PROCTOSIGMOIDITIS: A STUDY OF THIRTY-SIX CASES.

(E.) de Esesarte, G. (Natl. Inst. Nutr., Mexico City, Mexico). *J. Int. Med. Res.* 2(5):355-358, 1974.

Clinical, endoscopic, and parasitological findings are reported for 36 patients (16 males and 20 females, aged 12-48 yr) with amebic proctitis treated with p.o. administration of tinidazole (2000 mg/day for 2 days). The clinical response relative to colic pain, bloody-mucus stools, tenesmus, and pain on abdominal palpation 5-10 days after commencement of treatment was excellent (asymptomatic) in 21 patients. Very good improvement was observed in 12 patients, slight improvement in 2, and no improvement in 1 case. Endoscopic findings in the same period showed a normal mucosa in 24 cases, congestive image without ulcers in 9 patients, a few ulcers in 2 cases, and abundant ulcers in 1 case. The trophozoite was isolated in only 2 cases. An evaluation after 30 days showed clinical, endoscopic, and parasitological cure in 31 patients. Three cases were therapeutic failures and 2 persons dropped out of the study. Side effects were observed in 2 cases and consisted of slight transitory nausea.

GENERAL

Regional Enteritis

9687 ISOLATED LEFT HYDRONEPHROSIS COMPLICATING ILEOCAECAL GRANULOMATOUS DISEASE. *(E.)* Kutcher, R.; Rosenbaum, A.; Messinger, N. H. (Albert Einstein Coll. Md., Bronx, N.Y.). *Br. J. Radiol.* 47(560):490-492, 1974.

A 21-yr-old man with a 4-yr history of granulomatous ileocolitis presented with fever and back and left leg pain. Barium enema studies confirmed that the disease was confined solely to the distal ileum and proximal ascending colon. Routine excretory urography revealed hydronephrosis of the left kidney accompanied by hydroureter to the level of the superior margin of the left sacral wing. A left psoas abscess was drained through a left-inguinal incision. Surgical exploration showed that the lack of right ureteric involvement was related to the extension of the fistulous tract through the leaves of the mesentery to its root, and from there selectively to the left retroperitoneal region where the abscess developed.

9688 A MORPHOLOGICAL ASSESSMENT OF IMMUNOREACTIVITY IN COLONIC CROHN'S DISEASE AND ULCERATIVE COLITIS BY A STUDY OF THE LYMPH NODES. *(E.)* Skinner, J. M; Whitehead, R. (Radcliffe Infirm., Oxford, England). *J. Clin. Pathol.* 27(3):202-206, 1974.

Mesenteric lymph nodes in total colectomy specimens from 68 patients with ulcerative colitis or Crohn's disease were assessed for immunological reactivity. Lymph node features on routine hematoxylin-eosin sections were classified as normal, reactive paracortical tissue, reactive lymphoid follicles, large lymphoid and plasma cells, sinus dilation, or granulomas. Statistical analysis showed no difference in the distribution of these features and hence function between the two groups. In both ulcerative colitis and Crohn's disease, a combination of morphological features indicates competence of both cellular and humoral mechanisms. Cell-mediated immunity was not diminished in Crohn's disease and the presence of granulomata did not constitute any special immunological group. Differences in immunological reactivity appeared to be more closely related to the presence of ulcers than to the disease involved, with less reactivity noted in the absence of ulceration. Immunohistochemical analysis showed that ulcerative colitis and Crohn's disease did not differ with regard to the level of IgA-, IgG-, and IgM-producing plasma cells in nodes.

9689 THE CLINICAL EFFECT OF SALAZOSULPHAPYRIDINE (SALAZOPYRIN^{R}) IN CROHN'S DISEASE. A CONTROLLED DOUBLE-BLIND STUDY. *(E.)* Anthonisen, P.; Barany, F.; Folkenborg, O.; Holtz, A.; Jarnum, S.; Kristensen, M.; Riis, P.; Walan, A.; Worning, H. (Gentofte Univ. Hosp., Hellerup, Denmark). *Scand. J. Gastroenterol.* 9(6):549-554, 1974.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.
